AS 2021:2015

Acoustics—Aircraft noise intrusion—Building siting and construction

This Australian Standard® was prepared by Committee EV-011, Aircraft Noise. It was approved on behalf of the Council of Standards Australia on 12 February 2015.
This Standard was published on 25 March 2015.

The following are represented on Committee EV-011:

- Airservices Australia
- Aircraft Noise Ombudsman
- Australian Acoustical Society
- Australian Airports Association
- Australian Association of Acoustical Consultants
- Australian Helicopter Industry Association
- Australian Local Government Association
- Australian Window Association
- Consult Australia
- Department of Defence
- Department of Infrastructure and Regional Development
- Department of Planning and Environment, NSW
- Department of Planning, WA
- Department of Planning, Transport and Infrastructure, SA
- Department of Transport and Main Roads, Qld
- Department of Transport, Planning and Local Infrastructure, Vic.
- Master Builders Australia
- National Acoustic Laboratories
- Northern Territory Planning Commission
- Planning Institute Australia
- Property Council of Australia
- University of New South Wales
- Urban Development Institute of Australia

This Standard was issued in draft form for comment as DR AS 2021:2014.

Standards Australia wishes to acknowledge the participation of the expert individuals that contributed to the development of this Standard through their representation on the Committee and through the public comment period.

Keeping Standards up-to-date

Australian Standards® are living documents that reflect progress in science, technology and systems. To maintain their currency, all Standards are periodically reviewed, and new editions are published. Between editions, amendments may be issued.

Standards may also be withdrawn. It is important that readers assure themselves they are using a current Standard, which should include any amendments that may have been published since the Standard was published.

Detailed information about Australian Standards, drafts, amendments and new projects can be found by visiting www.standards.org.au

Standards Australia welcomes suggestions for improvements, and encourages readers to notify us immediately of any apparent inaccuracies or ambiguities. Contact us via email at mail@standards.org.au, or write to Standards Australia, GPO Box 476, Sydney, NSW 2001.

ISBN 978 1 76035 005 5

PREFACE

This Standard was prepared by the Standards Australia Committee EV-011, Aircraft and Helicopter Noise, to supersede AS 2021—2000.

This Standard provides guidance on the siting and construction of buildings in the vicinity of airports to minimize aircraft noise intrusion. The assessment of potential aircraft noise exposure at a given site is based on the Australian Noise Exposure Forecast (ANEF) system (for processes and details of this system refer to Appendices A and B).

This edition provides expanded aircraft noise tables and incorporates various associated amendments to the text. A new Appendix has been added to describe the process that should be followed in producing an Australian Noise Exposure Forecast (ANEF) chart for use in applying this Standard.

The term ‘informative’ has been used in this Standard to define the application of the appendix to which it applies. An ‘informative’ appendix is only for information and guidance.

CONTENTS

Page

FOREWORD

Aircraft noise intrusion within a building depends substantially on—

(a) the location, orientation and elevation of the site relative to the aircraft flight paths;

(b) the types and frequency of aircraft operating from the aerodrome;

(c) meteorological conditions;

(d) the types of activity (including sleep) to be, or being, accommodated in the building;

(e) the type of layout, construction and ventilation used; and

(f) the internal acoustic environment.

The data contained in the aircraft Noise Level Tables (Tables 3.4 to 3.58) are based on modelling, which in turn is based on actual measurements and are estimates of the noise levels emitted by the aircraft currently operating. These data will be amended as new aircraft are commissioned and as otherwise necessary.

Exposure prediction below 25 ANEF may be significantly inaccurate, and therefore caution should be exercised in the evaluation of locations outside the 25 ANEF contour. In addition, the extent of noise reduction required for a building may depend in part on the amount of noise from sources other than aircraft. Because of these factors and of the special acoustic requirements of certain types of building, it will sometimes be necessary to undertake supplementary noise measurements so that a sufficiently representative prediction of the noise exposure at the site under evaluation can be obtained. This is also true for aerodromes at which a significant number of training circuits occur. Such measurements should be performed only by personnel appropriately qualified in acoustics.

Human reaction to aircraft noise is known to depend not only on the amount of noise, but also on psychosocial factors such as personal sensitivity to noise, fear of aircraft crashing and attitudes towards aviation. Thus some individuals will be seriously disturbed by aircraft noise even when the building is sited and constructed according to this Standard.

This Standard has been developed to assist in building construction and land use planning in the vicinity of airports. It is not intended as a guide to the presentation of information about aircraft noise to the general public. A Handbook that is in preparation at the time of releasing this Standard will be developed by Standards Australia describing ways in which such information should be provided.

Some experience has shown that communities that are newly-exposed to aircraft noise (e.g. as a result of the construction of new runways, or the redesign of flight paths near an aerodrome) tend to be more sensitive to such noise than communities that are accustomed to it. Land use planning must by necessity use a long-term horizon, and the building siting acceptability recommendations in this Standard are based on the reactions of noise-accustomed communities. Regulatory authorities are cautioned that a transient heightened reaction could result from substantial new noise exposure.

STANDARDS AUSTRALIA

Australian Standard

Acoustics—Aircraft noise intrusion—Building siting and construction

SECTION 1 SCOPE AND GENERAL

1.1 SCOPE

This Standard, together with the relevant Australian Noise Exposure Forecast (ANEF) chart or locality map available for the aerodrome under consideration, provides guidelines for determining—

(a) whether the extent of aircraft noise intrusion makes building sites 'acceptable', 'unacceptable' or 'conditionally acceptable' for the types of activity to be, or being, undertaken (Clause 2.3);

(b) for 'conditionally acceptable' sites, the extent of noise reduction required to provide acceptable noise levels indoors for the types of activity to be, or being, undertaken; and

(c) the type of building construction necessary to provide a given noise reduction, provided that external windows and doors are closed (see Note 1).

This Standard deals specifically with noise from take-off, landing and circuit training operations at civil aerodromes or military airfields.

The acceptability of outdoor spaces is not covered by this Standard.

NOTES:

1 The recommendations for building construction are based on the assumption that external windows and doors are shut. If external windows or doors are opened for ventilation or other purposes, the noise attenuation values for various components given in Clause 3.3 will not be achieved. Item (c) above implies that mechanical ventilation will need to be installed when external windows and doors are shut to provide adequate protection against aircraft noise intrusion. Whether or not sufficient ventilation can be achieved by mechanical or other means should be considered before the selection of building components described in Clause 3.3.

2 There may be a significant increase in costs incurred in buildings designed to provide higher than normal noise attenuation for their type.

1.2 OBJECTIVE

This Standard is concerned with land use planning and building treatments in the vicinity of an airport. The objective is to provide guidance to regional and local authorities, organizations, communities and others associated with urban and regional planning and building development on the siting and construction of new buildings against aircraft noise intrusion and on the acoustical adequacy of existing buildings in areas near aerodromes.

This Standard is not intended to be applied for the purposes of assessing the effects of noise from aircraft. However, it should be noted that the effects of noise from aircraft are not confined to areas where the noise exposure exceeds 20 ANEF and may occur at or below 20 ANEF (see Appendix A for a description of the ANEF system).

1.3 APPLICATION

Application of this Standard should be considered when a building site may be affected by aircraft noise.

Reference to the appropriate ANEF chart will be necessary to determine the applicability of the recommendations of this Standard.

Section 2 of this Standard gives guidelines for determining the acoustical acceptability of a particular site.

Section 3, used in sequence with Section 2, gives guidelines for determining the extent of noise reduction and type(s) of construction required for a particular building.

A high level of skill is required to comply with many of the provisions of this Standard. Unsuccessful designs may be difficult and expensive to remedy. Inferior aircraft noise attenuation performance resulting from unsatisfactory design and construction will detract from the value and usefulness of a building throughout its life. It is expected that the provisions of this Standard will be interpreted by a qualified acoustician experienced in the characteristics of aircraft noise.

NOTES:

1 A flow chart setting out the various steps contained in this Standard is shown in Figure 1.1.

2 A worked example of the application of the Standard is given in Appendix C.

1.5 DEFINITIONS

For the purpose of this Standard, the definitions below apply.

1.5.1 Aerodrome

An area of land or water (including any buildings, installations and equipment)—

(a) established as an aerodrome under Air Navigation Regulations; or

(b) the use of which as an aerodrome is authorized under the regulations made under the *Civil Aviation Act 1988*; and

being such an area intended for use wholly or partly for the arrival, departure or movement of aircraft.

NOTE: The Department of Defence often refers to an aerodrome as an airfield.

1.5.2 Aircraft noise level

The arithmetic average of the maximum sound levels occurring during a series of flyovers by a specific aircraft type and load conditions measured in A-weighted decibels [dB(A)] using the S time-weighting of a sound level meter.

NOTES:

1 Derivation of the aircraft noise levels in Tables 3.4 to 3.58 is covered in Notes to Tables 3.1(A) and 3.1(B).

2 Internationally, aircraft noise is measured using slow (S) time-weighting, and the extensive databases and programming algorithms used in determining aircraft noise exposure levels use data based on S time-weighted measurements. Consistent with these practices, aircraft noise measurements and assessments in Australia use S time-weighting and an average of the maximum noise levels.

3 Maximum noise levels will vary from time to time depending on the prevailing meteorological conditions.

4 Throughout this Standard the notation dB(A) is used to describe A-weighted sound pressure level, whether this expresses a maximum sound pressure level, an average of maximum sound pressure levels, or a logarithmic average of A-weighted sound pressure levels as in the unit L_{Aeq}. Although this is not consistent with recommendations from the International Standards Organisation, which recommends the use of the notation dB in circumstances where the frequency weighting is clear, the notation dB(A) is used consistently in Australia, including in previous versions of this Standard, and it is believed that a change in notation would lead to unnecessary confusion and uncertainty.

1.5.3 Aircraft noise reduction (ANR)

A calculated or measured value. For design purposes, the arithmetic difference between the aircraft noise level at a site and the indoor design level, as described in Clause 3.2.2. For measurement purposes, the difference between the exterior and indoor sound levels as determined in accordance with Appendix D.

1.5.4 Airfield

An area of land or water (including any buildings, installations and equipment) established in accordance with military standards and requirements and intended for use wholly or partly for the arrival, departure or movement of aircraft.

1.5.5 Airport

An aerodrome with significant facilities.

1.5.6 Australian Noise Exposure Forecast (ANEF)

A single number index for predicting the cumulative exposure to aircraft noise in communities near aerodromes during a specified time period (normally one year).

NOTE: The computation of this index includes—

(a) measurements of aircraft noise (expressed in Effective Perceived Noise Decibels, EPNdB), which take account of the spectral, temporal and spatial aspects of the noise;

(b) estimates and generalizations of aircraft type groups and mix, number of operations, runway utilization, flight paths and operational procedures; and

(c) time of day, i.e. whether daytime (0700 hours to 1900 hours) or evening/night-time (1900 hours to 0700 hours).

This single number index is useful for rating the compatibility of various land uses with respect to aircraft noise. For this purpose, equivalent ANEF values at individual positions around an aerodrome are combined on a map to form ANEF contours. (See Appendices A and B for a description of the ANEF system and the method for its determination.)

1.5.7 Building site

The location of a proposed or existing building not associated with the aerodrome.

1.5.8 Indoor design sound level

The recommended maximum level in dB(A) inside a building from an aircraft flyover.

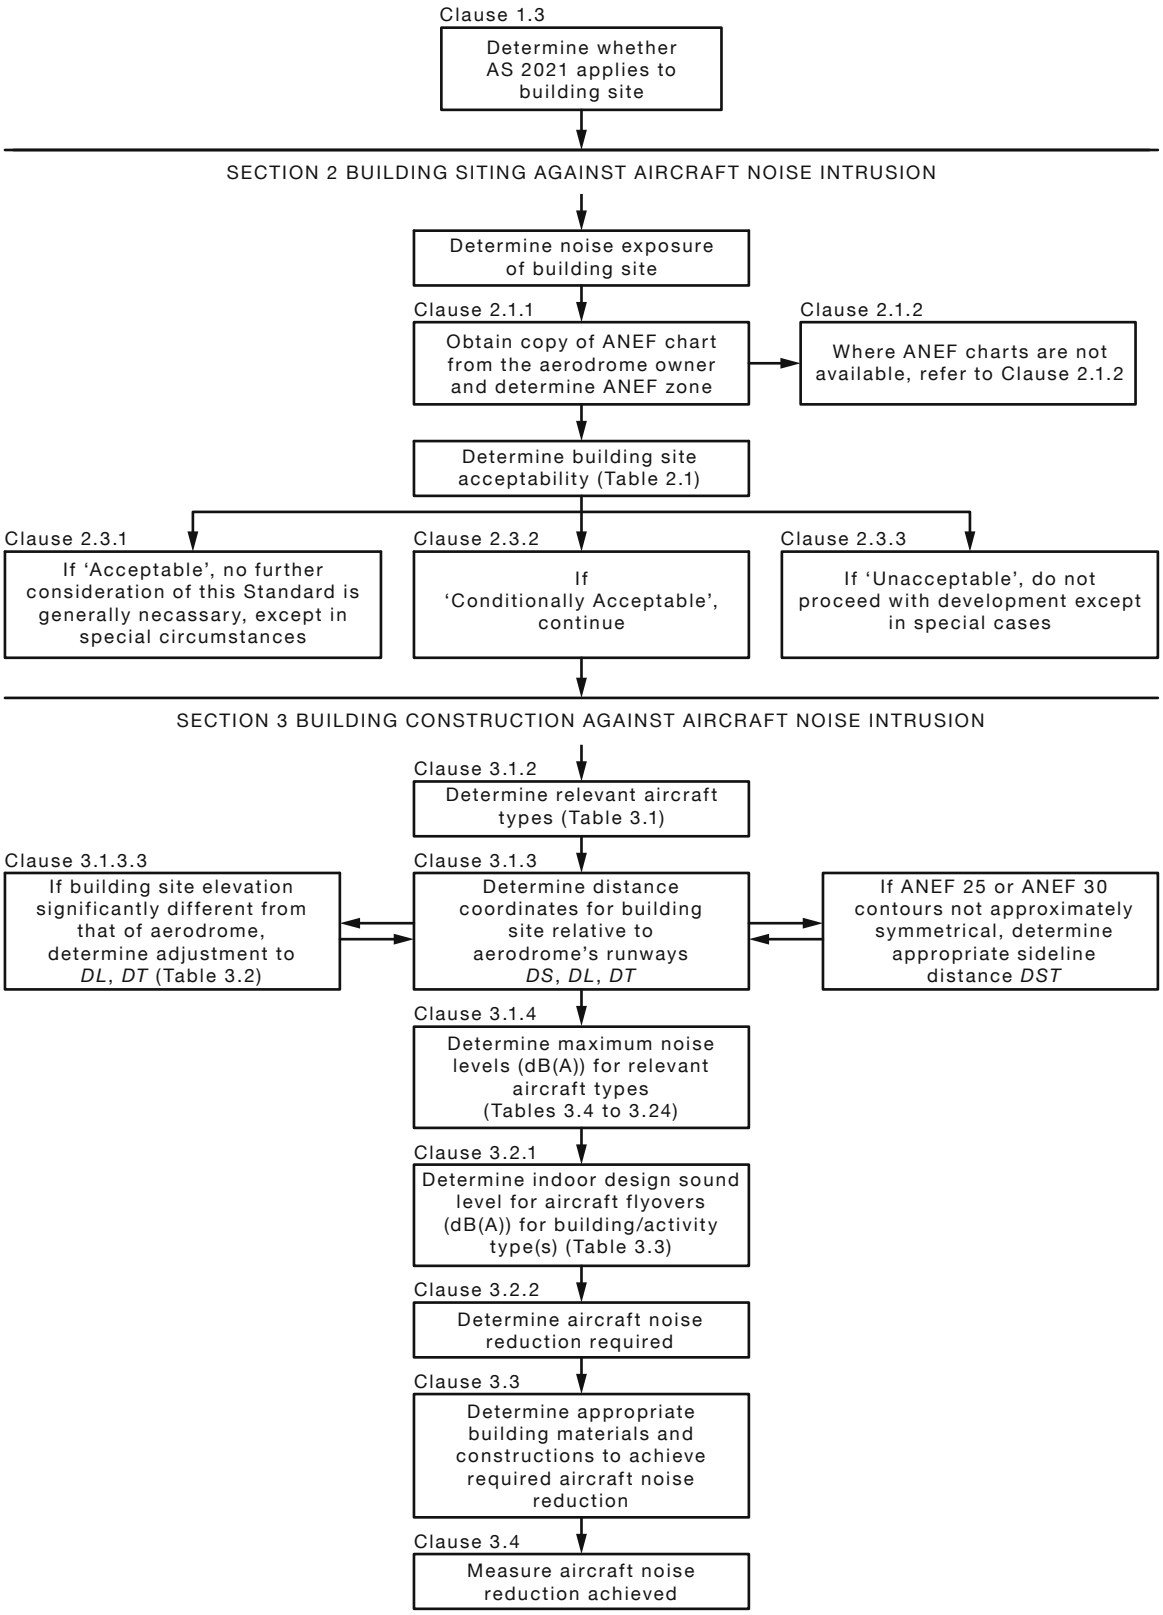

FIGURE 1.1 FLOW CHART

SECTION 2 BUILDING SITING AGAINST AIRCRAFT NOISE INTRUSION

2.1 DETERMINATION OF NOISE EXPOSURE OF BUILDING SITE

2.1.1 Aerodromes with ANEF charts

ANEF charts for the major Australian city airports, military aerodromes and for many of the country aerodromes are available from the appropriate authorities. All or some of the noise exposure contours of 20, 25, 30, 35 and 40 ANEF are shown on these charts.

These contours indicate land areas around aerodromes which are forecast to be exposed to aircraft noise of certain levels as defined in Clause 1.5.6; the higher the ANEF value the greater is the noise exposure.

Locate the position of the building site on the ANEF chart and determine the highest value ANEF contour which crosses the building site.

If the building site is outside the 20 ANEF contour, noise from sources other than aircraft may dominate; therefore, there is usually no need to proceed further in this Standard as the construction of the building need not specifically be designed to provide protection against aircraft noise intrusion. Nevertheless, if it is desired that premises be insulated against aircraft noise, the procedures of this Standard may be followed.

NOTES:

1 The individual aerodrome operators should be approached regarding the availability of ANEF charts.

2 For certain highly specialized building types such as auditoria or recording studios, specialist acoustic advice should always be sought.

2.1.2 Aerodromes without ANEF charts

The ANEF system takes account of noise levels, frequency and time of day of aircraft noise events. Therefore it is always preferable to use an ANEF chart to predict aircraft noise exposure at a site. If one does not exist, the preparation of an ANEF chart for the particular aerodrome should be requested through the aerodrome owner.

Where aerodrome usage is confined to a small number of civil, non-jet aircraft movements the production of an ANEF chart may not be justified and is unlikely to occur. In these cases refer to Appendix E.

2.2 DETERMINATION OF BUILDING SITE ACCEPTABILITY

2.2.1 General

The acceptability of the building site is dependent on the type of building proposed and on the ANEF zone in which it is to be located.

2.2.2 Determination of acceptability

For the particular building type under consideration, determine from Table 2.1 the building site acceptability, i.e. acceptable, conditionally acceptable or unacceptable, for the ANEF zone in which it is to be located.

2.3 ACTION RESULTING FROM ACCEPTABILITY DETERMINATION

2.3.1 Acceptable

If from Table 2.1, the building site is classified as ‘acceptable’, there is usually no need for the building construction to provide protection specifically against aircraft noise. However, it should not be inferred that aircraft noise will be unnoticeable in areas outside the ANEF 20 contour. (See Notes 1, 2 and 3 of Table 2.1.)

2.3.2 Conditionally acceptable

If from Table 2.1, the building site is classified as ‘conditionally acceptable’, the maximum aircraft noise levels for the relevant aircraft and the required noise reduction should be determined from the procedure of Clauses 3.1 and 3.2, and the aircraft noise attenuation to be expected from the proposed construction should be determined in accordance with Clause 3.3 (see Notes 1 and 3 of Table 2.1).

2.3.3 Unacceptable

If, from Table 2.1 the building site is classified as ‘unacceptable’, construction of the proposed building should not normally be considered. Where in the community interest redevelopment is to occur in such areas, e.g. a hotel in the immediate vicinity of an aerodrome, refer to the notes to Table 2.1.

TABLE 2.1

BUILDING SITE ACCEPTABILITY BASED ON ANEF ZONES
(To be used in conjunction with Table 3.3)

Building type	ANEF zone of site		
	Acceptable	Conditionally acceptable	Unacceptable
House, home unit, flat, caravan park	Less than 20 ANEF (Note 1)	20 to 25 ANEF (Note 2)	Greater than 25 ANEF
Hotel, motel, hostel	Less than 25 ANEF	25 to 30 ANEF	Greater than 30 ANEF
School, university	Less than 20 ANEF (Note 1)	20 to 25 ANEF (Note 2)	Greater than 25 ANEF
Hospital, nursing home	Less than 20 ANEF (Note 1)	20 to 25 ANEF	Greater than 25 ANEF
Public building	Less than 20 ANEF (Note 1)	20 to 30 ANEF	Greater than 30 ANEF
Commercial building	Less than 25 ANEF	25 to 35 ANEF	Greater than 35 ANEF
Light industrial	Less than 30 ANEF	30 to 40 ANEF	Greater than 40 ANEF
Other industrial	Acceptable in all ANEF zones		

NOTES:

1 The actual location of the 20 ANEF contour is difficult to define accurately, mainly because of variation in aircraft flight paths. Because of this, the procedure of Clause 2.3.2 may be followed for building sites outside but near to the 20 ANEF contour.

2 Within 20 ANEF to 25 ANEF, some people may find that the land is not compatible with residential or educational uses. Land use authorities may consider that the incorporation of noise control features in the construction of residences or schools is appropriate (see also Figure A1 of Appendix A).

3 There will be cases where a building of a particular type will contain spaces used for activities which would generally be found in a different type of building (e.g. an office in an industrial building). In these cases Table 2.1 should be used to determine site acceptability, but internal design noise levels within the specific spaces should be determined by Table 3.3.

4 This Standard does not recommend development in unacceptable areas. However, where the relevant planning authority determines that any development may be necessary within existing built-up areas designated as unacceptable, it is recommended that such development should achieve the required ANR determined according to Clause 3.2. For residences, schools, etc., the effect of aircraft noise on outdoor areas associated with the buildings should be considered.

5 In no case should new development take place in greenfield sites deemed unacceptable because such development may impact airport operations.

SECTION 3 BUILDING CONSTRUCTION AGAINST AIRCRAFT NOISE INTRUSION

3.1 AIRCRAFT NOISE LEVEL

3.1.1 General

The procedure for estimating the aircraft noise level likely to be experienced at the building site involves—

(a) the determination of the aircraft types forecast to be operating at the aerodrome near the building site;

(b) the graphical determination of a set of distance coordinates which describe the position of the building site relative to the aerodrome, and thus are an estimate of the position of the building with respect to that of aircraft during take-off, landing and circuit training operations; and

(c) the prediction of the aircraft noise level to which the building site will be exposed.

3.1.2 Determine aircraft types

Refer to Column 1 of Table 3.1(A) and Table 3.1(B). Identify all those aircraft types and operations (take-offs, landings and training circuits) forecast in the ANEF to occur on each runway and the times of operation. The aircraft types forecast to operate are given in the aircraft type tabulations included on ANEF charts. Where the aerodrome does not have an ANEF chart, refer to the aerodrome operator to determine appropriate aircraft types.

3.1.3 Determine distance coordinates for building site relative to aerodrome runways

3.1.3.1 *Aircraft using straight approach and departure flight paths*

The distance coordinates are determined as follows:

(a) On the appropriate ANEF chart or locality map, extend the centre-line of each runway to a point beyond the building site.

All runways should be taken as relevant and the procedures given carried out to determine the noise levels from aircraft movements on all runways.

(b) As shown in Figure 3.1, draw a line perpendicular to the extended runway centre-line and passing through the building site, known as ‘sideline projection’.

(c) Determine for each runway—

(i) *DS*, the distance in metres from the building site to the extended runway centre-line along the line drawn in Item (b);

(ii) *DL*, the distance in metres from the closer end of the runway to the intersection of the extended runway centre-line and the line drawn in Item (b); and

(iii) *DT*, the distance in metres from the further end of the runway to the intersection of the runway centre-line and the line drawn in Item (b).

3.1.3.2 *Aircraft using curved approach and departure tracks*

Where curved flight paths occur, the combined effects of aircraft altitude (as it proceeds along the curved flight path), site elevation, and sideline distance need careful consideration. It is recommended that a series of computations should be performed for a number of positions along the curved segment of the flight path with respect to the building site, and not just for the position closest to the building site.

See Figure 3.2. The distance coordinates are determined as follows:

NOTE: The following procedure should be adopted only if the details used to describe the curved flight paths for the production of the ANEF are known. The individual aerodrome operators should be approached regarding the availability of flight track information.

(a) On the appropriate ANEF chart or locality map, plot the closest relevant curved flight paths for each runway to a point beyond the building site. All runways should be taken as relevant and the procedures given carried out to determine the noise levels from aircraft movements on all runways.

(b) As shown in Figure 3.2, draw a line perpendicular to the flight path or its tangent and passing through the building site, known as 'sideline projection'.

(c) Determine *DST* and *DSL*. *DST* and *DSL* are the parts of the flight path which follow the centre-line from the end of the runway (see Figure 3.2).

(d) Determine *DC*. *DC* is that part of the flight path which is curved (see Figure 3.2). *DC* can be calculated using the following equation:

$$DC = \frac{2\pi RA}{360} \quad \ldots 3.1$$

where

A = the angle shown in Figure 3.2, in degrees

R = the radius shown in Figure 3.2, in metres

(e) Determine for each runway—

(i) *DS*, the distance in metres from the building site to the curved flight path along the line drawn in Step (b);

(ii) *DL*, the distance in metres obtained by adding *DSL* and *DC*; and

(iii) *DT*, the distance in metres obtained by adding *DST* and *DC*.

3.1.3.3 *Land height correction*

If the elevation of the building site differs from that of the aerodrome by ±10 m or more, the distance coordinates *DL* and *DT* must be corrected in accordance with Table 3.2 to take account of this difference.

Site elevations above or below that of the aerodrome are listed in Column 1 of Table 3.2 and the corresponding values to be subtracted from, or added to, *DL* and *DT* are given in the Columns 2 to 5. If the elevation of the aerodrome is greater than that of the site, the values given in Table 3.2 are to be added to *DL* and *DT* and if it is less they are to be subtracted from *DL* and *DT*.

NOTE: ANEF charts will include the effect of topography. To determine difference of elevation between the aerodrome and building site refer to a survey map of the area.

3.1.4 Determine aircraft noise levels [dB(A)]

The aircraft noise levels are determined as follows:

(a) For each relevant aircraft type listed in Table 3.1(A) and Table 3.1(B), identify the associated noise level table in the series Tables 3.4 to 3.58. The set of tables should be listed.

(b) For each noise level table in the set, and for each relevant aircraft operation, read off a corresponding noise level for the appropriate centre-line and sideline distance coordinate as follows:

(i) For take-off noise level tables, use *DT* and *DS* distance coordinates.

(ii) For landing noise level tables, use *DL* and *DS* distance coordinates.

(c) List the set of noise levels, and from the set select the highest value. This is the aircraft noise level to be used to determine the aircraft noise reduction required (see Clause 3.2.2). The only exception is where there is evidence that the particular aircraft type and movement which produced that noise level do not constitute a typical operation. In this case, select the next highest value from the noise tables.

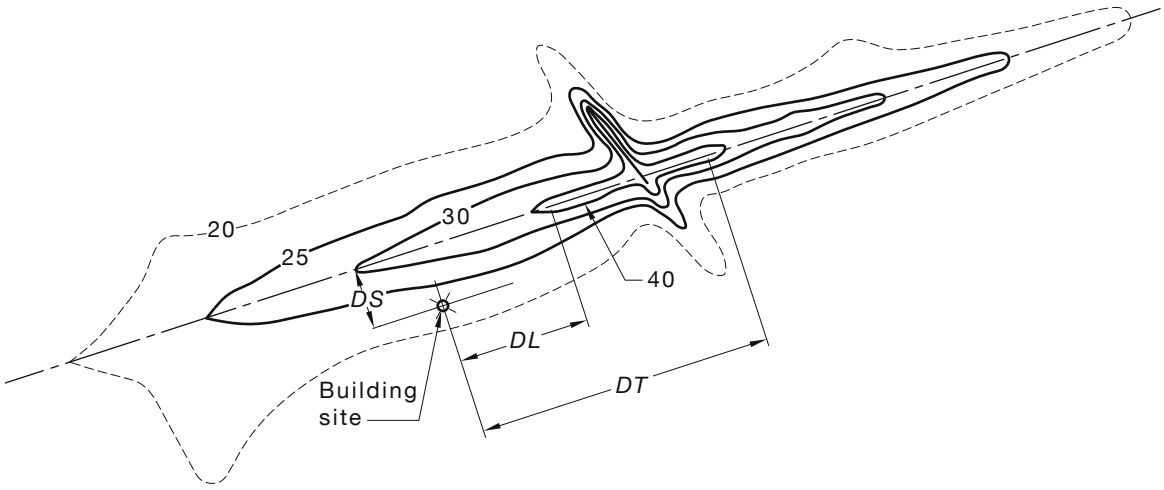
NOTES:

1 To establish that particular ANR values have been achieved, testing may be required. In these circumstances, the aircraft noise levels used for the design of the building construction should be taken as the higher of measurements taken at the site by an acoustic specialist, using procedures described in Appendix D, and tabulated levels given in this Standard.

2 The noise levels in Tables 3.4 to 3.58 are based on modelling and measurements. The tabulated values are estimates of the aircraft noise levels emitted by typical aircraft operating in Australia. Uncertainties in the data increase as the distances *DT*, *DL*, and *DS* increase.

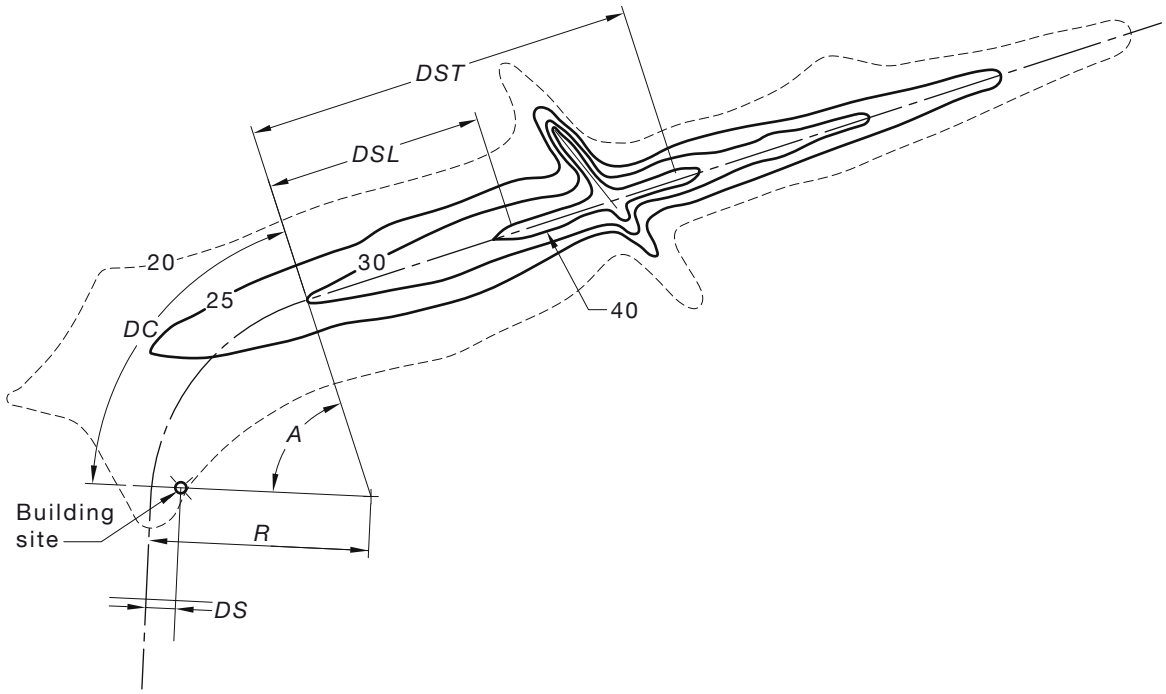
3 For some building sites, an aircraft noise level table may not include a value for a particular pair of distance coordinates determined in accordance with Clause 3.1.3. If this is the case, it indicates that the take-off or landing noise for the aircraft type being considered will not generally be of significance in terms of noise reduction requirements at that site.

4 Noise levels from helicopters are more difficult to determine than those from fixed wing aircraft, because their flight tracks and operating parameters depend significantly on local conditions. For this reason it is not considered possible to use tables such as Tables 3.4 to 3.58 to determine external noise levels from helicopters at a building site. The indoor design sound levels in Table 3.3 are applicable to noise from helicopter operations. However, where helicopters may possibly contribute the loudest noise events at a building site, expert advice should be sought to determine their maximum external noise levels before applying the remaining procedures in Clauses 3.2 to 3.4 of this Standard.



DIMENSIONS IN ANEF UNITS

FIGURE 3.1 DETERMINATION OF *DS*, *DL* AND *DT* FOR STRAIGHT FLIGHT PATHS



DIMENSIONS IN ANEF UNITS

FIGURE 3.2 DETERMINATION OF *DS*, *DL* AND *DT* FOR CURVED FLIGHT PATHS

3.2 NOISE REDUCTION REQUIREMENTS

3.2.1 Determine indoor design sound level for aircraft flyovers

From Table 3.3, select the indoor design sound level appropriate for the activity or building type under consideration.

3.2.2 Determine aircraft noise reduction (*ANR*) required

Subtract the level obtained in Clause 3.2.1 from the aircraft noise level determined in accordance with Clause 3.1.4. The resulting value is an estimate of the extent of aircraft noise reduction (*ANR*), in decibels, to be incorporated in the building's envelope.

NOTES:

1 In any one building, several different activity and space types may be accommodated, necessitating the selection of several indoor design sound levels and noise reductions, as appropriate. See also notes to Table 3.3.

2 For building sites that require an *ANR* in excess of 30 it is recommended that for the purpose of noise control the assessment be evaluated in terms of the spectral components of the aircraft noise rather than a dB(A) value, so as to take account of low frequency components of the aircraft overflight that may influence the internal dB(A) level.

3.3 CONSTRUCTION GUIDELINES

Buildings on sites determined to be 'conditionally acceptable' under Clause 2.2 should be designed such that the ANR values determined under Clause 3.2.2 are achieved for all internal spaces. In general, this will require that external windows and doors be kept closed, since if these are opened for ventilation purposes the aircraft noise reduction of the building envelope will be significantly reduced. If it is necessary to close windows and doors to comply with this Standard, building ventilation should be in accordance with the National Construction Code on the assumption that windows and doors are not openable. Mechanical ventilation or airconditioning systems complying with AS 1668.2 should be installed.

Various rooms in a building may require different indoor design sound levels and consequently different ANR values (see Clause 3.2). In addition, the areas of external building components may differ between rooms. For this reason, determination of appropriate building components should be performed separately for each room within a building. In some cases, an external perimeter approach to design may be appropriate (see Note 6 to Table 3.3).

NOTE: Appendix F provides guidance on achieving high levels of acoustic insulation against aircraft noise.

If internal doors within a building need to be opened for functional reasons, then noise transmission from other internal spaces should also be taken into account in determining the overall ANR for each room.

In general, specialist acoustic advice will need to be sought to ensure that the sound transmission loss of all individual building components is appropriate to achieve the required ANR values. Possible sound transmission through vents and other openings should also be considered in the design.

Appendix G provides one method for determining appropriate building materials and constructions to achieve a required ANR value. Appendix G is intended to serve as a guide to the types of construction which would be necessary in any instance. Other specific building materials may also be suitable, and alternative building designs which optimize noise attenuation may also be developed to achieve the required performance.

3.4 COMPLIANCE TEST

In situations where measurement of noise attenuation is required following construction, testing by an acoustics specialist following the method described in Appendix D, is recommended.

If the measured ANR is equal to or greater than the design ANR determined in accordance with Clause 3.2 the building as constructed complies with this Standard [see Appendix D, Paragraph D4(m)].

NOTES TO TABLES 3.1(A) and 3.1(B):

1 The aircraft types given in Tables 3.1(A) and 3.1(B) represent the civil aircraft types flying in Australia at the time of preparation of this Standard. For types not given, an aircraft type of similar size and configuration may be selected.

2 For civil aircraft that are not similar in size and configuration to those listed, the appropriate noise levels may be obtained by contacting Air Services Australia.

3 For military aircraft, the appropriate noise levels should be obtained by contacting the Department of Defence.

4 Where a single table is used to represent a number of aircraft types, noise levels shown in the relevant table represent the highest value in each case.

5 As the climb rate, and hence the spread of noise levels, is affected significantly by the aircraft take-off weight, data have been included for international aircraft for long (>8000 km) and short (900 to 1800 km) haul take-offs. For any given set of site coordinates, both take-off tables should be checked, and the higher of the two noise levels used for design purposes, provided that this corresponds to an operation that is relevant at that point.

6 The noise levels given in Tables 3.4 to 3.58 represent average maximum levels. Therefore there may be individual flights that produce higher or lower levels than those tabulated.

7 The noise levels shown in Tables 3.4 to 3.58 were calculated using the INM modelling program, version 7.0d. Calculations were for straight approach and departure tracks, with standard profiles. The runway was of an adequate length for the relevant aircraft operation, flat topography was used, and meteorological conditions were 15°C, 760 mm-Hg and 14.8 km/h headwind (INM defaults). They represent maximum A-weighted noise levels (using ‘Slow’ speed rectification) as estimated by the INM program.

TABLE 3.2
LAND HEIGHT CORRECTIONS

metres

Difference in elevation between site and aerodrome	Distance in metres to be added to *DT* and *DL*, if site is below the aerodrome, or subtracted from *DT* and *DL*, if site is above the aerodrome			
	Landing (correction to *DL*)	Take-off (correction to *DT*)		
	All aircraft type groups	Domestic jet aircraft types	International aircraft types	Domestic propeller-driven aircraft and light aircraft types
10	190	60	80	110

70	1 330	410	530	780
75	1 420	440	570	840
80	1 520	470	600	890
85	1 610	500	640	950
90	1 710	530	680	1 000
95	1 800	560	720	1 060
100	1 900	590	750	1 120

NOTES:

1 This Table is based on a 3° glide slope for landing, and an average climb gradient has been assumed for take-off.

2 Interpolation between values is permissible.

TABLE 3.3

INDOOR DESIGN SOUND LEVELS* FOR DETERMINATION OF AIRCRAFT NOISE REDUCTION

Building type and activity	Indoor design sound level*, dB(A)
Houses, home units, flats, caravan parks	
Sleeping areas, dedicated lounges	50
Other habitable spaces	55
Bathrooms, toilets, laundries	60
Hotels, motels, hostels	
Relaxing, sleeping	55
Social activities	70
Service activities	75
Schools, universities	
Libraries, study areas	50
Teaching areas, assembly areas (see Note 5)	55
Workshops, gymnasia	75
Hospitals, nursing homes	
Wards, theatres, treatment and consulting rooms	50
Laboratories	65
Service areas	75
Public buildings	
Churches, religious activities	50
Theatres, cinemas, recording studios (see Note 4)	40
Court houses, libraries, galleries	50
Commercial buildings, offices and shops	
Private offices, conference rooms	55
Drafting, open offices	65
Typing, data processing	70
Shops, supermarkets, showrooms	75
Industrial	
Inspection, analysis, precision work	75
Light machinery, assembly, bench work	80

* These indoor design sound levels are not intended to be used for measurement of adequacy of construction. For measurement of the adequacy of construction against aircraft noise intrusion see Appendix D.

NOTES TO TABLE 3.3:

1 The indoor design sound levels in Column 2 are hypothesized values based on Australian experience. A design sound level is the maximum level (dB(A)) from an aircraft flyover which, when heard inside a building by the average listener, will be judged as not intrusive or annoying by that listener while carrying out the specified activity. Owing to the variability of subjective responses to aircraft noise, these figures will not provide sufficiently low interior noise levels for occupants who have a particular sensitivity to aircraft noise.

2 Some of these levels, because of the short duration of individual aircraft flyovers, exceed some other criteria published by Standards Australia for indoor background noise levels (see AS/NZS 2107).

3 The indoor design sound levels are intended for the sole purpose of designing adequate construction against aircraft noise intrusion and are not intended to be used for assessing the effects of noise. Land use planning authorities may have their own internal noise level requirements which may be used in place of the levels above.

4 For opera and concert halls and theatres, and for recording, broadcast and television studios and similar buildings where noise intrusion is unacceptable, specialist acoustic advice should always be obtained.

5 Certain activities in schools may be considered particularly noise sensitive and 50 dB(A) may be a more desirable indoor sound level to select for any teaching areas used for such activities. However, the effect of other noise sources should be considered.

6 The provisions of this Standard relating to different internal design sound levels for different indoor spaces could result in the use of different construction and materials in contiguous spaces, and require the construction of substantial barriers between habitable spaces, e.g. heavy self-closing internal doors, detracting from the amenity of the building. Therefore consideration should be given to a uniform perimeter insulation approach.

APPENDIX A

AUSTRALIAN NOISE EXPOSURE FORECAST SYSTEM

(Informative)

A1 GENERAL

The aircraft Noise Exposure Forecast (NEF) technique was first developed in the United States of America in the late 1960s. It was subsequently redefined in Australia in 1982.

The NEF system is a scientifically based computational procedure for determining aircraft noise exposure levels around aerodromes. It can be used for assessing average community response to aircraft noise and for land use planning around aerodromes. In the Australian NEF system, noise exposure levels are calculated in Australian Noise Exposure Forecast (ANEF) units, which take into account the following features of aircraft noise:

(a) The intensity, duration, tonal content and spectrum of audible frequencies of the noise of aircraft take offs, approaches to landing, and reverse thrust after landing (for practical reasons, noise generated on the aerodrome from aircraft taxiing and engine running during ground maintenance is not included).

(b) The forecast frequency of aircraft types and movements on the various flight paths, including flight paths used for circuit training.

(c) The average daily distribution of aircraft arrivals and departures in both daytime and night-time (daytime defined as 0700 hours to 1900 hours, and night-time defined as 1900 hours to 0700 hours).

ANEF charts are provided for most aerodromes throughout Australia. The charts are simply plans of the aerodrome and the surrounding localities on which noise exposure contours of 20, 25, 30, 35 and 40 ANEF units have been drawn. These contours indicate land areas around an aerodrome which are exposed to aircraft noise of certain levels as defined by Clause 1.5.6; the higher the ANEF value the greater the noise exposure.

In the areas outside 20 ANEF, noise from sources other than aircraft tends to predominate over aircraft noise, although individual reactions to aircraft noise may differ markedly. Within the area from 20 ANEF to 25 ANEF, aircraft noise exposure starts to emerge as an environmental problem, while above 25 ANEF the noise exposure becomes progressively more severe.

The land use compatibility recommendations made in this Standard relate to the above ANEF contours.

In 1979, the then Department of Transport together with the Department of Defence jointly sponsored the National Acoustic Laboratories (NAL) of the Department of Health in undertaking a major socio-acoustic investigation to assess the impact of aircraft noise on residential communities in Australia. In the social survey, personal interviews were conducted with 3575 residents around the major airports in Sydney, Adelaide, Perth and Melbourne, and the RAAF Base Richmond, NSW. From the responses to the questionnaire, subjective reaction to aircraft noise was measured in terms of general reaction (GR), a composite of a number of ratings of dissatisfaction, annoyance and fear, as well as reports of activity disturbance and complaint disposition. A high score of GR was used to define whether or not respondents were ‘seriously affected’ by aircraft noise. Noise measurements were made at several sites around each airport either by tape-recording fly overs or by the unmanned logging of noise levels over periods of two weeks. The noise exposure at each of the dwellings in the social survey was estimated in terms of 20 different noise indices.

Analysis by NAL showed that 'equal-energy' indices such as NEF were more highly correlated with community reaction than other types of index, including 'peak-level' indices. However, it was found that the standard weighting given to night flights was too high, and that there should be a weighting applied to flights during evening hours. Attitudes towards the aviation industry, personal sensitivity to noise, and fear of aircraft crashing were found to be important in modifying the extent to which a person will be affected by a given amount of aircraft noise. Demographic variables, such as age, sex, occupation and education, were found to be of generally minor importance in explaining subjective reaction.

The report of NAL's extensive and definitive study was published in 1982*. As a result of NAL's findings, the Department of Aviation decided to revise its existing American-based NEF system to reflect the specific Australian findings. The system was renamed the ANEF system. The following changes were included in the new system:

(i) The 'night-time' period was changed from between 2200 hours and 0700 hours to between 1900 hours and 0700 hours. The weighting of noise in the 'night' hours was lowered from 12 dB to 6 dB.

(ii) The 20 ANEF contour was included on all ANEF charts.

(iii) Tabulations of aircraft movements and runway usages were included on ANEF charts.

The findings of the NAL survey also provided information on the percentage of residents living around established aerodromes who are either moderately or seriously affected by aircraft noise. Such information, which is called a dose/response relationship, provides the basic information necessary for formulating appropriate recommendations on compatible land use around Australian aerodromes.

Prior to 1982, Australian land use recommendations were essentially similar to the criteria used in the U.S. NEF system. However, with the availability of an Australian dose/response function derived from the NAL social survey, the U.S. criteria were revised to take into account the general reaction of Australian communities to aircraft noise.

In essence, this revision was limited to a firmer definition of the criterion for residential land use compatibility. In the NEF system as originally adopted in Australia, the U.S. criterion of 30 NEF was adhered to, but, in accordance with a recommendation of the House of Representatives Select Committee on Aircraft Noise made in 1970, cautious restraint was urged to be applied by land zoning authorities when applying the system to Australian conditions. Where possible, the 25 NEF contour was used rather than the 30 NEF as a conservative safeguard until the system was validated in Australia.

The NAL Report provided substantial evidence to support the use of 25 ANEF as the appropriate criterion for residential land usage. The 25 ANEF as a residential land usage criterion was recommended in 1985 by the House of Representatives Select Committee on Aircraft Noise, and subsequently adopted as policy by the Commonwealth Government. The only qualification which arises from the findings of the NAL Report is that some people will find that the noise exposure at 25 ANEF is still unacceptable (refer to Figure A1 for the percentage of people affected in the 20 ANEF to 25 ANEF zone). Accordingly, the issuing authorities enter the 20 ANEF contour on all ANEF charts. It is to be stressed, however, that the actual location of the 20 ANEF contour is difficult to define accurately, because of variations in aircraft flight paths, pilot operating techniques, and the effect of meteorological conditions on noise propagation. For that reason, the 20 ANEF contour is shown as a broken line on ANEF charts.

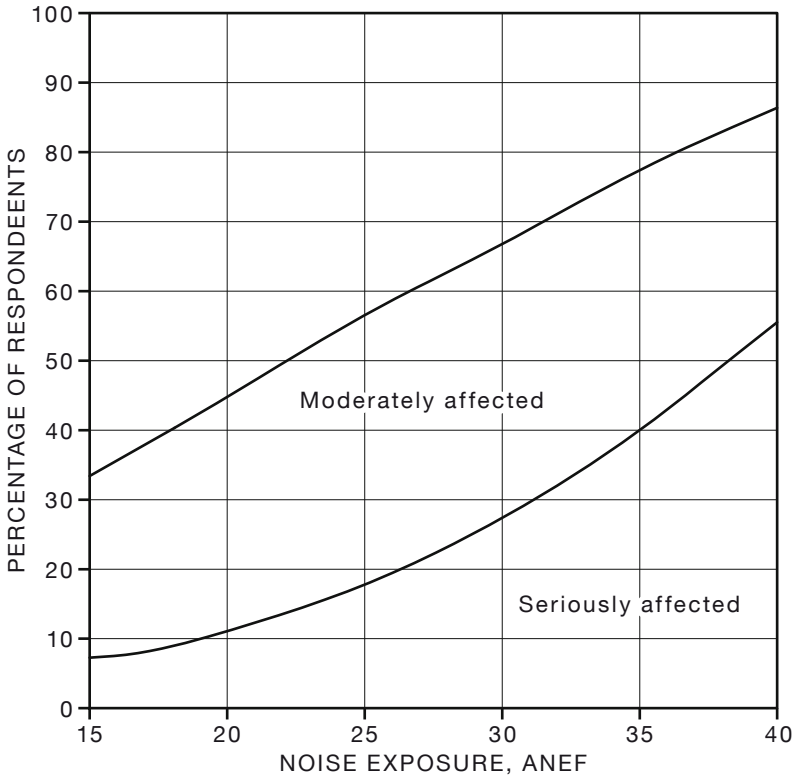
---

* HEDE, A.J. and BULLEN, R.B. *Aircraft Noise in Australia: A Survey of Community Reaction*, National Acoustic Laboratories Report No. 88. Australian Government Publishing Service, Canberra, February 1982.

Land use planning is a function carried out by State or local government authorities in all but the Commonwealth Territories. It is realized that many unrelated, non-aviation factors have to be taken into account and could influence decisions taken in specific land use considerations. The land use recommendations in Table 2.1 are most readily applicable to new development on undeveloped land around aerodromes. In those areas around some of the major Australian airports where established residential development has existed for some considerable time, it is generally not feasible to apply appropriate land use criteria unless the opportunity for rezoning of individual properties arises.

Figure A1 shows the dose/response relationship between aircraft noise and community reaction derived from the NAL Report. This figure indicates that significant community reaction may occur for exposures below 20 ANEF. Experience has shown that newly exposed communities may exhibit a higher reaction than that suggested by the curves in Figure A1. ANEF values average noise exposure over a year and do not take account of variations in noise exposure patterns to which the community reacts on an hourly, daily, weekly or seasonal basis. To address this issue, other parameters such as maximum noise levels and frequency of noise events may be included in noise assessment of airports to supplement ANEF levels.

The land use recommendations in the ANEF system are given in Table 2.1. Paragraph A2 is a technical description of the ANEF formulation. Paragraph A3 describes the different types of aircraft noise contour charts prepared using the ANEF system.



NOTE: This graph was derived from the National Acoustic Laboratories Report No. 88.

FIGURE A1 RELATIONSHIP BETWEEN NOISE EXPOSURE FORECAST LEVEL AND COMMUNITY REACTION IN RESIDENTIAL AREAS

A2 THE ANEF FORMULA

A2.1 General

The ANEF system is based on survey evidence of the reaction of Australian communities to aircraft noise. The ANEF unit incorporates, in a single equation, the noise levels produced by the various aircraft operating at an airport, plus a logarithmic function of the daily average number of aircraft noise events, with a weighting included if they occur during the evening or night-time hours when the sensitivity of people to noise is increased. The forecast frequency of aircraft movements on various flight paths (either take off, landing or touch-and-goes), and the proportion of aircraft movements by day and by night, provides the input to determine this aircraft number weighting factor.

The basis for combining aircraft noise levels with a logarithmic function of frequency of occurrences is called the principle of energy equivalence. Briefly, this principle holds that people respond to a number of noise events in the same way as they react to their loudness, and therefore the number of noise events should also be expressed in logarithmic form. This implies that a loud noise perceived only a few times per day produces similar subjective response to a moderate noise perceived many times. Most social surveys, including the Australian survey by the National Acoustic Laboratories, have confirmed that 'equal energy' units of aircraft noise exposure are better correlated with community reaction than are other units known as peak-level indices which have also been postulated for aircraft noise exposure measurement.

The ANEF combines the above two factors of aircraft noise (i.e. noise level and frequency of operations) by a mathematical formula. Noise of evening/night operations (defined as 1900 hours to 0700 hours in the ANEF system) of aircraft is weighted to account for the increased sensitivity of communities to noise during periods of relaxation or sleep. The actual aircraft noise level measurement used in the ANEF formulation is the complex Effective Perceived Noise Level (EPNdB) which takes into account annoying aspects in both the temporal and frequency domains. (The EPNdB unit is also used for the international noise certification of new aircraft). Its calculation is complex but its principles are fairly basic.

The three basic physical properties of noise are measured: level, frequency distribution and time variation. Specifically, the instantaneous sound pressure level in each of 24 one-third octave bands of the noise is gathered for each one-half second increment of time during the aircraft fly over. The following are then computed:

(a) The instantaneous one-third octave levels are converted to perceived noise level by reference to a subjective annoyance table (NOY table).

(b) A tone correction factor is calculated to account for spectral irregularities.

(c) A duration correction factor is calculated.

(d) The EPNdB is the algebraic addition of the maximum perceived noise level of the overflight plus the tone and duration corrections.

A2.2 Formula derivation

Noise levels of most civil transport aircraft, military aircraft and a representative sampling of light aircraft now operating in Australia, are known with a reasonable degree of accuracy. Aircraft manufacturers in the USA and Europe provide accurate noise definitions of their products. Additionally, aircraft noise data have been collected over the years from airport noise-monitoring systems at major airports, and from measurements of light and military aircraft noise.

The noise information, together with aircraft performance information giving the aircraft's height, speed and engine power level at the various stages of its take off or arrival flight path, are incorporated into the aircraft noise modelling computer software.

If the flight path of an aircraft is known, the typical noise level at any point along and to the side of the flight path can be calculated. If the aircraft flies that operation on the same flight path N_d times in daytime hours and N_n times in evening/night-time hours, the partial ANEF value due to that aircraft type on that particular flight path can be calculated from the following equation:

$$ANEF_{ij} = EPNdB_{ij} + 10 \log_{10} (N_d + 4\ N_n) - 88 \quad \ldots A1$$

where

$ANEF_{ij}$ = noise exposure due to aircraft type i on flight path j

$EPNdB_{ij}$ = noise level of aircraft type i on flight path j

N_d, N_n = number of flights during the day and night respectively, of aircraft type i on flight path j

The figure '88' is an arbitrary constant chosen so that ANEF numbers typically lie in a range where they are not likely to be confused with other noise ratings.

It can be seen from Equation A1 that if there were only one aircraft flight, in daytime hours only, then the partial ANEF value would be directly proportional to the noise level of the aircraft. Also, it can be seen that the ANEF increases as the logarithm of the number of operations increases. The total ANEF at any point on the ground around an aerodrome is composed of all individual noise exposures (summed logarithmically) produced by each aircraft type operating on each flight path over the period of one day as follows:

$$ANEF = 10 \log_{10} \sum_{i-1}^{i=I} \sum_{j-1}^{j=J} \text{anti} \log_{10} \left(\frac{ANEF_{ij}}{10} \right) \quad \ldots A2$$

where

I = total number of aircraft types

J = total number of flight tracks

$ANEF$ = noise exposure forecast

In line with many other acoustic descriptors, the ANEF value is a logarithmic value.

A2.3 Traffic forecasts and flight path allocation

The ANEF method is sensitive to the forecast of air traffic movements and to the allocation of such air traffic to the flight paths on which departing and arriving aircraft are routed. Every attempt is made to ensure that the traffic forecast and flight paths are as accurate as possible. However, at major airports particularly, accurate definition of flight paths to the extent of the 20 ANEF contour is difficult to achieve. For that reason, the confidence in the location of the 20 ANEF will be less than for the 25, 30, 35 and 40 ANEF contours.

The ANEF computation is based on forecasts of air traffic movements on an average day. Allocations of the forecast movements to runways and flight path are on an average basis and take into account the existing and forecast air traffic control procedures at the airport which nominate preferred runways and preferred flight paths for noise abatement purposes (as described in Air Services Australia Aeronautical Information Publications). Aircraft movements are categorized by—

(a) night or day;

(b) type of aircraft;

(c) take off, landing or touch-and-go;

(d) range;

(e) runway used;

(f) flight path; and

(g) if applicable, circuits.

A2.4 Military aircraft operations

In preparing ANEFs for Defence airfields, it is necessary to include an assessment of the projected aircraft operations. This projection includes planned and forecast operations and incorporates allowances for possible future military aircraft activities in order to maintain the operational requirements of the airfields. All allowances are based on policies which address both the capability of the airfield to sustain such activities and the future strategic requirements of the airfield relating to its role in the defence of Australia.

In many cases the military flying activities conducted at Defence airfields may be limited to weekdays. Consequently, a daily movement average based on 365 days of activity per year, as assessed for civil aerodromes, may not be appropriate when producing the ANEF for military airfields and joint Defence/civil airports. When military flying activities at an airfield are expected to occur for less than 365 days per year, average daily movement numbers for military aircraft may be assessed on the basis of average aircraft movements during operating days only. In the case of increased activity during exercise periods, the estimated movements may be averaged on the number of days planned for the exercises and included as an average aircraft movement in the ANEF.

Factors influencing the forecast aircraft operations may change during the term of the ANEF in response to the ongoing review of Australia's defence requirements.

A3 TYPES OF AIRCRAFT NOISE CONTOUR CHARTS

There are three different types of aircraft noise contour charts produced using the ANEF system. All three types of chart are prepared using the same computational procedures. The differences arise from the types of data which have been input to produce the following charts:

(a) *ANEF—Australian Noise Exposure Forecast*

This is a contour map showing the forecast of noise exposure levels that will exist in a future year. It may be for a particular year, generally about 10 years from the date of issue, or in the case of some of the busier civil airports, it may represent the airport operating at 'ultimate capacity'. It is based on a firm forecast of aircraft movement numbers and operating times, aircraft types, destinations, flight paths and a given use of runways at the aerodrome.

The ANEF chart is the only one of the three types of chart which is intended to have status in land use planning decisions. It will have been subjected to review by relevant authorities before release, and the chart will display the official endorsement of Air Services Australia or the Department of Defence. Only one ANEF chart for a given aerodrome can be current at any one time. A more recently endorsed chart supersedes an earlier chart.

(b) *ANEI—Australian Noise Exposure Index*

This is a contour map based on historical data from a previous year, where exact numbers and types of aircraft which used the aerodrome are known. It shows the average daily aircraft noise exposure around the aerodrome for that year.

ANEI charts are used principally as benchmarks or indicators of change of aircraft noise exposure.

(c) *ANEC—Australian Noise Exposure Concept*

This is a noise contour map which may be produced during consideration of options for aerodrome development. It is based on a hypothetical set of conditions of runways, aircraft types and so on, and there may be several ANEC charts prepared for the same future year. It may be a supposition for a long way into the future, and may never occur.

Because it has a hypothetical basis and may not have been subject to review by relevant authorities, an ANEC chart is not intended for use for land use planning purposes.

APPENDIX B

AUSTRALIAN NOISE EXPOSURE FORECAST PROCESS AND PROCEDURE

(Informative)

B1 SCOPE

This Appendix describes the process that should be followed in producing an Australian Noise Exposure Forecast (ANEF) chart for use in applying this Standard. This scope does not include legislative requirements that may apply to the production of an ANEF chart. Aerodrome operators should undertake appropriate research to establish the legislative requirements in their jurisdiction.

The basis of the ANEF unit itself, and its relationship with reaction to aircraft noise, is described in Appendix A.

The major stakeholders who draw on the information provided in ANEFs are as follows:

(a) *Aerodrome operators*—for whom an ANEF chart fulfils legislative requirements and assists in identifying areas where sensitive development should be discouraged where it is not compatible with aircraft noise. This is intended to minimize potential land use conflicts, and to ensure the long term sustainability and development of aerodrome operations.

(b) *Land use planning authorities*—which use ANEF charts and have regard to this Standard to assist with current and future land use planning decisions, strategies and policies.

(c) *State and territory agencies*—which have regard to the ANEF system and this Standard in formulating state planning policies and developing regional strategies.

(d) *Property developers*—who refer to ANEF charts as a tool to identify where possible state/territory and local government planning restrictions may apply when making significant investment decisions, and also to determine any required noise mitigation measures for a proposed development.

(e) Members of the general public who currently live or own land within or close to the published ANEF contours, or propose to do so, and who should be aware that noise related planning or rezoning restrictions may apply to their land.

B2 PROVISIONS FOR DEVELOPMENT OF ANEF CHARTS

B2.1 General

To be recognized under this Standard, an ANEF needs to be endorsed by Air Services Australia or, in the case of military airfields, an appropriate authority within the Commonwealth Department of Defence.

B2.2 Allowance for future infrastructure and seasonal effects—Composite ANEF

Appendix A describes three types of noise contour chart:

(a) ANEF.

(b) ANEC.

(c) ANEI.

In general, an ANEF chart will be based on an ANEC chart, following endorsement and consultation procedures as described below. However, in two specific cases, the ANEF chart should be prepared as a composite of a number of ANECs.

First, where future runways are proposed and included in the aerodrome's master plan or other strategic planning documents, an ANEC with the new runway arrangements might not cover areas that are impacted by current operations on runways that may be closed or downgraded in the future. Therefore, an ANEC for the existing runway system 'at capacity' or immediately prior to commissioning of a new runway system should be combined with the ANEC for the future runway system. An example of this is the Melbourne Airport ANEF, which is a composite of four ANECs: one ANEC with the existing two-runway system, two ANECs with three runways (parallel E-W runways and another with parallel N-S runways, as it was not known in which order they would be commissioned) and finally an ANEC with a four runway (N-S and E-W parallels at capacity) system.

Second, where there are strong seasonal effects, which cause contours to shrink or grow depending on runways in use, the ANEF chart should be a composite of two 'worst three months' sets of contours (worst three months based on one wind direction/runway usage and worst three months for another).

In both cases the methodology used to aggregate the composite ANEF should be clearly described in material provided with the ANEF chart (see Paragraph B2.3).

Note that composite ANEFs should only be produced in one of the two circumstances described above. They should not be produced to unreasonably expand the ANEF contours by adopting, for example, a range of alternative flight paths using the same runway configuration.

B2.3 Military aircraft movements

Many aerodromes have relatively small numbers of military aircraft movements, which generally have a minor impact in terms of aircraft noise. However, joint user aerodromes have significant numbers of military and civil movements that must both be included in a combined ANEF. At some airfields, the contribution of military movements to the ANEF is even more significant.

The nature of civil and military operations is often quite different. In particular, military operations can be highly seasonal, with peaks in times of military exercises.

In these cases, the definition of an 'average day' used in the formulation of ANEF input data should be carefully considered with a view to ensuring that movements during peak periods are not unduly 'averaged out'. The methodology used to define the 'average day' should be clearly described in material provided with the ANEF chart (see Paragraph B2.4).

B2.4 Transparency of assumptions for ANEF charts

B2.4.1 *General*

It is desirable to provide major stakeholders with a level of transparency for ANEF charts, to allow understanding of the inputs that have informed the ANEF modelling.

In this regard, aerodrome operators are encouraged to be as open and transparent as possible in making information and underlying assumptions available. Although there may be data elements that are commercially confidential, the assumptions underlying the presented chart, and the basis for its calculation, should be clearly described. In the case of military airfields, these requirements will also be subject to considerations of national security, as certain inputs to the ANEF may include classified material.

To be considered acceptable as an ANEF chart for use in conjunction with this Standard, an endorsed ANEF chart should be accompanied by information describing the inputs, assumptions and methodologies underlying the ANEF, suitable for public release. This required information is described in the following sections.

B2.4.2 *The ANEF chart*

All ANEF charts should be labelled clearly with the following:

(a) The type of ANEF (standard, long range, or ultimate capacity).

(b) The ANEF forecasted year (if applicable).

The ANEF type label should always be clear or obvious.

The ANEF chart should include a North Compass and scale.

The map, which forms the major part of the ANEF chart, should include a base map and ANEF contours. The map should be presented in a form acceptable to the relevant approval authority, and should be readily reproducible in either paper or electronic form. The base map should be clear while not intruding on the ability to read the contours. The base map should include labels for local suburbs and areas of importance.

The 20 ANEF contour should be presented in a different way from the other contour lines on the ANEF map. Most maps use a dashed line to represent the 20 ANEF contour.

Contours can be shaded to clearly distinguish each ANEF zone. It is recommended that the shading is transparent if this approach is taken to ensure that the base map is clearly visible.

ANEF values should be clearly labelled on each contour. The values should be bold, with contrasting colour to the actual contour itself.

When an ANEF chart is endorsed by Air Services Australia, information regarding the number of aircraft operations on each runway is required to be included on the chart.

Runway diagrams can also be shown on the ANEF chart to show the orientation of the existing or proposed runway system. These runway diagrams can also be shown separately with arrows to illustrate the different modes of operation (e.g. Sydney Noise Sharing Modes).

B2.4.3 *Movement growth forecasts*

The time horizon, growth assumptions and methodology for the preparation of the forecasts should be included at the appropriate level of detail.

The relationships between the key drivers and movement forecasts should be explained. Key drivers may include the following:

(a) Projected movement growth.

(b) Aircraft fleet changes.

(c) Proposed airport infrastructure changes (e.g. runway extensions, taxiways etc.).

(d) Increased tourism markets.

(e) Economic factors such as the regional economy and GDP.

(f) Strategic land use context.

Movement trends are best shown in a graphical format to show the change in movements over the forecasting horizon. A trends graph should incorporate both historical and forecast aircraft movements.

Movements should be broken down into the main segments such as—

(i) international;

(ii) domestic/regional;

(iii) general aviation;

(iv) freight; and

(v) helicopters.

Capacity movement forecasts look at the potential number of movements based on the physical and operational constraints of the ultimate development of the aerodrome in the future. Where the ANEF is based on ultimate capacity, the basis for the capacity calculation will have been included in documentation provided to Air Services Australia or the Department of Defence as part of the endorsement process. A summary of this calculation at the appropriate level of detail with associated commentary, tables, graphs or diagrams (e.g. for modes of runway operation) should be included.

B2.4.4 *Movement profiles*

Aircraft movement daily profiles show the number of aircraft movements per hour over the course of the day. In actual operations, it is the hourly movements (or 15-minute blocks) that are important in balancing movements between runways and selection of runway modes of operation where there are choices. It is also used in determining when a runway system is considered to be at capacity.

Although the movement profile is not a direct input into the ANEF calculation, it assists in supporting some key assumptions affecting the ANEF contours.

Movement profiles show trends of peak movement times during the day, and are useful and informative in comparing projected profiles (which may, for example, assume peak spreading as movement numbers grow) to existing profiles.

Movement profiles should be illustrated in a graphical format, plotting the number of aircraft movements against the time of day.

B2.4.5 *Fleet mix tables*

Tables should be provided showing the mix of aircraft types included in the modelling.

There are various methodologies for projecting the future mix of aircraft types at an aerodrome. The prediction should include consideration of industry trends, future airlines, new routes and the appropriate equipment to operate on such routes (thick or thin, long or short haul etc.). The basis of the forecast and general trends should be included in the narrative where appropriate.

Where an aircraft type has no equivalent in the software used for ANEF calculation, the type that was used as a substitute in the calculations should be shown and justified. This applies particularly to any assumed future aircraft types.

B2.4.6 *Daily aircraft movements by type and runway*

The ANEF computation is based on forecast movements on an average day. This ANEF ‘average day’ is not a specific day, but is generally calculated as the number of annual movements divided by 365. However, there may be variations in this, as described in Paragraphs B2.2 and B2.3.

The allocation of these movements to runways can be performed using a number of procedures, ranging from simple (e.g. assume the future split is the same as the existing) to very complex (e.g. modelling of future airport operating mode availability using meteorological data and a synthetic future schedule of movements). The methodology used should be described to an appropriate level of detail.

Predicted daily aircraft movements should be presented in a table showing day and night movements (arrivals, departures and, if relevant, circuits) for each aircraft type used in calculations, for each runway. If the ANEF chart is a composite from a number of ANEC charts, as described in Paragraph B2.2, then separate tables should be provided for each ANEC.

Note that when an ANEF chart is endorsed by Air Services Australia it is a requirement that this information be included on the ANEF chart.

B2.4.7 *Aircraft tracks and movements by track*

In ANEF calculations, aircraft movements on a single runway will typically be assigned to one of a number of tracks, depending on factors that may include the direction of the port of origin or destination, the aircraft type, and the time of day.

Information accompanying the ANEF chart should include diagrams showing all tracks used in the calculation, and a description of the procedures used to assign aircraft to those tracks. If 'track dispersion' is applied to allow for variation in actual tracks about the average location, this should also be described.

For smaller aerodromes it would be appropriate to include a table listing the number of movements on each track, by aircraft type and time of day (day or night). For larger aerodromes, where several hundred tracks are typically used in modelling, such a listing may be more confusing than informative. However, sufficient information should be provided to allow an understanding of features of the ANEF contours that depend on the distribution of aircraft between tracks.

B3 PREPARATION OF AN ANEF CHART

Preparation of an ANEF chart should include consideration of the following:

(a) Appropriate aircraft types have been selected.

(b) Correct substitution of group aircraft.

(c) Operational suitability of runway usage, flight path data and destinations.

(d) Forecast aircraft movements are not greater than the safe capacity of the aerodrome.

(e) Weather and terrain assumptions, if nominated, are correct.

(f) Airspace limitations.

(g) Feedback from consultation.

APPENDIX C

EXAMPLE OF APPLICATION OF THIS STANDARD

(Informative)

A single-storey house is to be built on a site that is approximately 10 km from a major international airport. Reference to the Standard confirms the likelihood of a problem from aircraft noise. As the site is within 15 km of the airport, the procedure described in the Standard is applied.

Clause

1.3 An ANEF chart applying to the airport is obtained from the airport owner for examination.

2.1 The site is located on the map between the 20 ANEF and 25 ANEF contours. Reference to Table 2.1 shows that this location is only 'conditionally acceptable', requiring further implementation of the provisions of the Standard. The almost certain need to have closed windows and alternative ventilation in exposed rooms is recognized and accepted.

3.1.2 All the aircraft types listed in Table 3.1(A) and Table 3.1(B) operate from the airport frequently throughout both day and night except for the hours when a curfew is in effect. It is necessary, therefore, to refer to all the Tables from 3.4 to 3.58 to determine the aircraft noise level which will be experienced at the site.

3.1.3 The coordinates of the site, which is 15 m above the airport with respect to the relevant runway, are as follows:

(a) DT = 6100 m.

(b) DL = 3500 m.

(c) DS = 200 m.

The corrections to be subtracted from DT because of site elevation are (from Table 3.2) 90 m, 110 m and 170 m. Hence DT becomes 6010 m, 5990 m, and 5930 m, according to the aircraft type to which it is to be applied. DL becomes 3210 m when corrected. DS remains 100 m.

3.1.4 The aircraft noise level at the site is determined by entering the corrected coordinates in Tables 3.4 through 3.58 (DT for departures and DL for arrivals). The aircraft noise level is found to be 92 dB(A) for a 747-400 (long haul) aircraft taking off.

3.2.1 The most critical indoor design level for the proposed house is 50 dB(A) (from Table 3.3) for habitable spaces. A bedroom on a corner is considered as a specific example of a space to be insulated.

3.2.2 The aircraft noise reduction (ANR) is 92 − 50 = 42 dB(A).

3.3 Use the procedure in Appendix G or another suitable method to determine the type of building construction which may be appropriate.

G1.2 Noise will enter the room through the ceiling, the external walls, and the windows. The bedroom is assumed to have two external walls with a window in each. The components of concern are the roof/ceiling, the walls, and the windows. In this example it is assumed that the floor is not elevated and not exposed to aircraft noise.

G2.2 For the room under consideration, there are three components, $N = 3$.

G2.3 The ceiling height is 2.75 m.

G2.4 The dimensions of the bedroom, the ratio of the areas of the components to the floor area are as follows:

Component	Dimension, m	Area, m^2	Ratio S_c/S_f
Ceiling (and floor)	4×3.5	14	1.0
Windows	2×1.5 (each of 2)	6.0	0.43
External walls	$(4 + 3.5) \times 2.75 - 6$	14.6	1.05

G2.5 The reverberation time (T) is taken to be 0.5 s.

G2.6 For the purpose of preliminary assessment, assume a value of 6 dB can be taken for K_c, for all components.

G2.7 The aircraft noise attenuation required of each component is determined from the equation:

$$ANA_c = ANR + 10 \log_{10} [(S_c/S_f) \times (3/h) \times 8TN] - K_c$$

The values for the roof/ceiling, external walls, and windows are as follows:

ANA_c roof/ceiling $= 42 + 10 \log_{10} (1 \times 1.09 \times 8 \times 0.5 \times 3) - 6$

$= 47$ dB(A)

ANA_c external walls $= 42 + 10 \log_{10} (1.05 \times 1.09 \times 8 \times 0.5 \times 3) - 6$

$= 47$ dB(A)

ANA_c windows $= 42 + 10 \log_{10} (0.43 \times 1.09 \times 8 \times 0.5 \times 3) - 6$

$= 43$ dB(A)

3.4 If required, following construction use the method described in Appendix D to measure the aircraft noise reduction achieved.

APPENDIX D

METHOD FOR MEASURING AIRCRAFT NOISE REDUCTION (*ANR*)

(Informative)

D1 SCOPE

This Appendix provides the recommended method for determining the aircraft noise reduction (*ANR*) for a completed building space. The method requires the simultaneous measurement of the maximum exterior and indoor sound levels during flyovers by the relevant aircraft under the relevant operating condition(s) as determined in Clause 3.1.4.

NOTES:

1 The noise levels in Tables 3.4 to 3.58 are based on modelling and measurements (see Note 2 to Clause 3.1.4). The exterior flyover noise levels measured according to this Appendix may differ from those determined according to Clause 3.1.4 because the values given in the tables are long-term average maximum values and it is not possible to confirm long-term maximum aircraft noise levels by a few short-term measurements taken on a particular day.

2 It is recommended that a minimum of five relevant aircraft overflights, and where practical ten overflights, be used for the determination of the ANR.

D2 INSTRUMENTATION

D2.1 General

The instrumentation required comprises one or more of the following:

(a) Type 1 sound level meters as specified in AS IEC 61672.1.

(b) Integrating-averaging sound level meters as specified in AS IEC 61672.2.

(c) Statistical analysers and data loggers with equivalent performance, in respect of frequency-weighting, time-weighting, statistical accuracy and tolerances, to Items (a) and (b).

(d) Storage devices, including but not limited to level recorders, magnetic tape recorders and digital event recorders, complying with the relevant requirements of AS IEC 61672.1 and AS IEC 61672.2.

Where any storage device, e.g. a magnetic tape recorder or digital event recorder, is used, take into account its effects on the accuracy of measurements.

NOTES:

1 Special care should be taken to ensure that the dynamic range of the instruments is large enough for the applications, and that the inherent electrical noise and overload capacity of these instruments are suitable.

2 The accuracy of the measurement will depend on the temporal characteristics of the sound being measured and the type of instrumentation being used. Care should be taken to achieve the required accuracy in any given circumstances.

D2.2 Calibration

The complete measuring system, including portable reference sound sources, should be calibrated over its full frequency and dynamic range by a certified calibration laboratory at intervals not exceeding 2 years (see AS IEC 61672.1 and AS IEC 61672.2).

D2.3 Field checks

Check the performance of the instrumentation periodically when in field use, and immediately before and after measurements are made. For extended measurement periods, perform the checks immediately before and after each measurement sequence. Use a pistonphone, portable reference sound source or other portable checking device appropriate to the sound level meter or other instrumentation to perform the checks. Except where the calibration signal cannot be excluded from the data, do not switch the instrument off between checks. In all cases, the operating instructions for the instrument should be followed carefully. If the instrumentation system registers a discrepancy equal to or greater than 1 dB between consecutive checks, any measurements in the interval between the two checks are considered invalid.

D3 MEASUREMENTS

D3.1 General

It is important that pertinent details of the measurement instruments, measurement procedure, and conditions prevailing during the measurements, are carefully recorded and kept for reference purposes. Reference to the relevant Standards should also be given.

NOTE: In some circumstances, an 'A' frequency-weighting is inadequate for filtering out high level infrasound, which occurs near some industrial locations and some forms of transport, as well as near buildings owing to wind turbulence. This may cause overload, and, if not detected, the resulting distortion produced at higher frequencies may be inaccurately attributed to audible sound.

D3.2 Measurement positions

D3.2.1 *Outdoor measurements*

Locate the external microphone either at a height of 1.2 ±0.05 m above the ground surface or at the level of the centre of the window for habitable rooms, with the microphone orientated to be at grazing incidence to the passage of the aircraft overflight. Do not locate the microphone any closer than 3.5 m from any reflecting surface other than the ground. Where possible, position the microphone to have an unobstructed view of the aircraft during the subject test overflight. Where this condition cannot be satisfied or requires the external microphone to be located at a significant distance from the building or room in question, use appropriate corrections to estimate the external noise level immediately outside the room in the absence of obstructions or reflecting surfaces. Describe the basis and extent of such corrections in the report.

D3.2.2 *Indoor measurements*

Perform measurements inside buildings at those locations at which the noise is of interest. It is recommended that measurements be made in the most exposed room for each category of internal space relevant to the building type. For larger, multiple-occupancy buildings, more than one occupancy may need to be tested. The preferred measurement positions are at least 1 m from the walls or other major reflecting surfaces, 1.2 m to 1.5 m above the floor, and about 1.5 m from windows.

NOTES:

1 Where measurements are made inside buildings, the importance of certain transmission paths, e.g. transmission through open or closed doors and windows, should be considered.

2 The presence of furnishings or other reflective surfaces, which may result in shielding or scattering of the noise, should also be considered.

3 Attention is drawn to the possibility of instrument overload due to strong low frequency components (see AS IEC 61672.1).

4 Where any mechanical ventilation system serving the indoor space emits sound within 10 dB(A) of the indoor design level determined in accordance with Table 3.3, the system should be turned off while the measurements are being made.

5 The space in which indoor measurements are made should be furnished normally for its use; if the space is unfurnished the indoor design sound levels will be higher and corrections should be made and reported.

D3.2.3 *Determination of aircraft noise reduction (ANR)*

Measure the maximum sound pressure level simultaneously outside (LA_{out}) and inside (LA_{in}) the relevant space during each relevant aircraft flyover using 'A' frequency-weighting and 'S' time-weighting. The arithmetic difference between LA_{out} and LA_{in} is the aircraft noise reduction for that flyover (ANR_n).

$$LA_{out} - LA_{in} = ANR_n \quad \ldots \text{D1}$$

The arithmetic average of all ANR_n values determined for that space is the ANR achieved.

NOTE: If the ANR achieved is more than 5 dB(A) below the design ANR, the envelope building components should be carefully examined to determine if they have been constructed strictly in accordance with the specifications.

D4 REPORTING OF RESULTS

Include the following items in the test report, where applicable:

(a) Location sketch showing measurement position(s) and relationship to aircraft overflights.

(b) A statement as to the location and height of microphones.

(c) For the indoor measurements, the microphone location and conditions of windows and doors (open or closed) and condition of the room (furnished or unfurnished).

(d) For the indoor measurements, the ambient background level prior to and after measurements, in addition to any extraneous noises that may have interfered with the indoor measurements. The condition of mechanical ventilation (on or off) should be recorded.

(e) For the outdoor measurements, the ambient level prior to and after measurements, and any extraneous noise that may have interfered with the measurement program.

(f) The weather conditions at the time(s) of the measurements including air temperature, relative humidity, barometric pressure and wind speed and direction, relative to the site.

(g) The airport terminal information service data, weather and operational procedures at the time(s) of the measurement(s) (if available).

(h) The times of day when measurements were made.

(i) The aircraft traffic flow, composition of aircraft types, and aircraft operations used for measurements.

(j) The instrumentation used, the date of its most recent calibration, and the type of performance checking procedures used.

(k) The external noise level used for design purposes, the internal noise level goals and the design ANR.

(l) The measurement results showing external noise levels (LA_{out}), internal noise levels (LA_{in}) and ANR_n for individual aircraft overflights, and the ANR achieved.

(m) A statement as to compliance with the aircraft noise reduction (ANR) requirements of this Standard certifying that the building as constructed complies with the Standard. (See Clause 3.4.)

APPENDIX E

METHOD FOR DETERMINING BUILDING SITE ACCEPTABILITY FOR LIGHT GENERAL AVIATION AERODROMES WITHOUT ANEF CHARTS

(Before proceeding refer to Clause 2.1.2)

(Informative)

E1 GENERAL

NOTE: Where aerodrome usage is confined to a small number of civil, non-jet aircraft movements the production of an ANEF chart may not be justified and is unlikely to occur. In these cases this Appendix should be referenced.

The acceptability of a building site for a particular building type depends on both the maximum aircraft noise level (see Section 3) and the average number of flights per day over the site.

E2 PROCEDURE

Determine from Clause 3.1 the aircraft noise levels to which the building site will be exposed. Compare the aircraft noise levels with the levels shown in Table E1 for the particular building type under consideration, and for the appropriate number of aircraft operations over the site.

TABLE E1

BUILDING SITE ACCEPTABILITY BASED ON AIRCRAFT NOISE LEVELS*

Number of flights per day	Aircraft noise level expected at building site, dB(A)		
	Acceptable	Conditionally acceptable	Unacceptable
House, home unit, flat, caravan park, school, university, hospital, nursing home			
>30	<70	70–75	>75
15–30	<80	80–85	>85
<15	<90	90–95	>95
Hotel, motel, hostel, public building			
>30	<75	75–80	>80
15–30	<85	85–90	>90
<15	<95	95–100	>100
Commercial building			
>30	<80	80–85	>85
15–30	<90	90–95	<95
<15	<100	100–105	>105

* The values in Table E1 are based on a small aerodrome with a small number of civil, non-jet aircraft movements. They should not be used in any other circumstances.

NOTE: The forecast daily average number of aircraft flights affecting the site should be obtained from the aerodrome owner. However, each night-time flight between 1900 hours and 0700 hours is to count as four operations.

E3 ACTION RESULTING FROM ACCEPTABILITY DETERMINATION

E3.1 Acceptable

If from Table E1 the building site is classified as ‘acceptable’, there is usually no need for the building construction to provide protection specifically against aircraft noise.

E3.2 Conditionally acceptable

If from Table E1 the building site is classified as ‘conditionally acceptable’, the required noise reduction should be determined in accordance with Clause 3.2, and the aircraft noise attenuation to be expected from the proposed construction should be determined in accordance with Clause 3.3.

E3.3 Unacceptable

If, from Table E1 the building site is classified as ‘unacceptable’, construction of the proposed building should not normally be considered (see Notes 4 and 5 to Table 2.1).

APPENDIX F

INSULATION AGAINST AIRCRAFT NOISE—DESIGN AND CONSTRUCTION CONSIDERATIONS

(Informative)

F1 GENERAL

This Appendix provides guidance on acoustic design for insulation against aircraft noise. It is based on experience gained to date in the Sydney Aircraft Noise Insulation Project for both new construction and retrofit installations.

The information presented is not intended to be exhaustive, but rather to alert designers to a number of factors that need to be taken into account in developing effective and practical designs. In particular, designers need to recognize—

(a) the nature and limitations of much of the available sound transmission data on building components; and

(b) the need to reconcile potentially competing requirements for acoustic performance, function, safety, amenity, and aesthetics.

Because of the noise levels involved and the nature of the noise spectrum, the design should be undertaken by an acoustical specialist with appropriate experience.

F2 SOUND TRANSMISSION DATA

F2.1 General

The most up-to-date information should be obtained on the noise insulation properties and weighted sound reduction index (R_w) of building components, and ongoing development of building components related to the level of attenuation achievable should be taken into account.

NOTE: For the majority of components, the value for weighted sound reduction index, R_w, is similar to the value for sound transmission class STC (see AS/NZS ISO 717.1).

In Australia, there are generally no universal systems to accredit the acoustic performance of products or components in field situations. In selecting components for acoustic insulation, designers usually have to rely on limited published information, particularly for absorption coefficients and R_w values. In many instances, such data are only available from manufacturers' trade literature; the original test results are not available to the designer. Designers should proceed with caution and should be aware of a number of potential difficulties as discussed below.

F2.2 Laboratory versus in situ performance

The data available to designers are usually based on laboratory measurements determined under idealized conditions. Thus they represent values which are unlikely to be attained in other circumstances. The reported R_w values are unlikely to be achieved in buildings because of imperfections in the detailing of the construction and in the actual construction, or because of the nature of the spaces. Therefore care in both design and construction is particularly important for those parts of the building on which reliance is to be placed to lessen the intrusion of noise. The extent of the degradation of R_w values will be variable. Of vital significance in this regard is the observation that the higher the R_w value potentially achievable by a sound barrier, the more significant is its degradation by quite minor imperfections.

F2.3 Importance of low frequencies

Jet aircraft noise in proximity to an airport tends to be dominated by low frequency components. As a result, R_w ratings alone are not a reliable guide to the attenuation properties of building components. It is possible for components with lesser R_w values to perform better at the critical low frequencies than components with higher R_w values. The full spectrum information for the building component should be consulted where an ANR in excess of 30 is required.

F2.4 Interpretation of test reports

Manufacturers often present their products for testing in a range of configurations such that reported test results do not represent the building component as it is subsequently manufactured and installed. This further complicates the assessment of a different in situ performance compared with one based on information derived from laboratory measurements (see Paragraph F2.2). Purchasers and those preparing specifications should endeavour to determine the precise conditions of test of the component whenever possible.

F2.5 Repeatability and reproducibility of test data

Different products are tested in different laboratories, each with its own characteristics such as size and shape of receiving and transmitting rooms. There is limited published data in Australia to assess the repeatability of test results for the R_w values of different types of materials, such as glass, the R_w values of windows, the absorption coefficients of insulating material, and the R_w values of materials in combination, such as plaster-clad stud walls. For example, some data suggest that the R_w value for the same window measured in more than one laboratory can vary by 3 dB.

F2.6 Confidence of test data

Designers need to be aware that in many instances the reported acoustic performance of a component is based on only one laboratory test report.

F3 DESIGN AND CONSTRUCTION CONSIDERATIONS

F3.1 General

In high noise areas, and in residences and smaller commercial and public buildings, the treatments to achieve the target ANR need to be considered in conjunction with requirements for function, amenity, safety and aesthetics. Examples encountered during retrofit installations include—

(a) excessive intrusion of secondary windows, or their opening sashes, into the functional space;

(b) failure of the associated hardware (window rollers, door locks, hinges and keepers) under the unusually heavy glazing loads;

(c) injury to users opening and closing heavy sashes;

(d) creation of trip hazards in doorways;

(e) injury to children as a result of the momentum of heavy doors;

(f) incompatibility of modern materials with period decor and finish;

(g) need to preserve heritage features of a building;

(h) personal intercommunication and the relationship of spaces;

(i) location, installation and maintenance of mechanical ventilation;

(j) seismic and structural integrity of building; and

(k) fire hazards due to electrical cabling becoming embedded in insulation material, or where insulation prevents the dissipation of heat from electrical appliances and fittings, especially down-lights.

F3.2 Planning

For new construction, greater efficiency and effectiveness are achieved by considering acoustic factors from the earliest planning stages. Decisions should be made early in the planning process regarding the acoustic perimeter, the type of mechanical ventilation and any zones for its operation and control, wall and roof systems best suited to the level of noise exposure, and aesthetically and functionally suitable window types and proportions. Careful attention to modular dimensions permits the use of available insulating materials—such as batts, boards, and membranes—with minimum additional expense. Judicious location of attached garages and roofed outdoor spaces can reduce the level of noise penetrating perimeter walls.

Insulation of an existing construction can be more costly than that of a new construction because of—

(a) the difficulty of gaining access to the areas requiring treatment;

(b) the need to fit components to non-modular spaces, resulting in wastage of material and additional effort in installation; and

(c) less flexibility in the choice of components because of the need to match existing features.

The functional requirements set out in Paragraph F3.1 should be considered during planning.

F3.3 Choice of elements

F3.3.1 *Roofs*

Pitched roofs with a voluminous ceiling space reduce noise more effectively than roofs with a ceiling which follows the form of the external sheeting. Larger roof voids can also accommodate ventilation equipment and ducts, and facilitate their subsequent maintenance. Over larger spans they can also be more readily strengthened to carry the extra weight of insulation and plant.

F3.3.2 *Fibrous insulation*

Fibrous insulation should exhibit the following properties:

(a) Long term stability such that the properties will not change over time. The insulation should not settle under its own weight, blow away, or be otherwise displaced.

(b) Adequate acoustic performance, which may depend on factors such as thickness, mass per unit volume, fibre diameter, and fibre disposition.

(c) Fire retardance.

(d) Insect and vermin resistance.

(e) Non-toxicity.

(f) Non-corrosiveness.

F3.3.3 *Flexible acoustic membranes*

Flexible acoustic membranes are an effective alternative to rigid board insulation, especially for retrofit application. They should exhibit the following properties:

(a) Long term stability, especially when subjected to high roof-space temperatures.

(b) Adequate acoustic performance, which may depend on the relative rigidity of the membrane, mass per unit area, thickness and porosity.

(c) Fire retardance.

(d) Insect and rodent resistance.

(e) Non-toxicity.

NOTE: The combustion products of flexible acoustic membranes should also be non-toxic.

F3.3.4 *Windows*

It is possible to purchase from a large range of laboratory tested acoustic windows for different applications (secondary only, new primary and secondary, new stand-alone) in different styles (sliding, double hung, awning, casement) and different materials (aluminium, wood, UPVC). The availability of product of proven quality should be established before design commences.

In choosing and installing windows, the primary functions of a window to exclude the weather and admit light should not be overlooked. Stand-alone windows, or any secondary windows installed externally, should be constructed to the requirements of AS 2047. Flashings should be properly detailed, water drains should be maintained, and original window sight lines should not be impeded. Windows should also conform to any local planning requirements. For example, new stand-alone windows are not permitted in some designated heritage precincts.

F3.3.5 *Doors*

Doors are an important visual element of a building. The character of an existing building can often be retained by carefully strengthening an existing door with panels of acoustic membrane and fixing laminated glass behind existing glazing.

F3.3.6 *Ventilation*

An acoustically insulated building must be kept virtually air tight to exclude external noise. Therefore mechanical ventilation or airconditioning is needed to provide fresh air and to control odours. Requirements for acceptable indoor-air quality are given in AS 1668.2. Recommended design sound levels for different areas of occupancy in buildings are given in AS/NZS 2107.

NOTES:

1 The requirements of AS 1668 should be viewed as applying also to Class 1 buildings as defined by the National Construction Code.

2 In domestic situations, the minimum requirements set out in AS 1668 are not always adequate to remove kitchen cooking odours or to control damp in older residences.

Rising damp can cause severe fungal growth when an insulated house is left closed for a prolonged period. A time-clock controlled ventilation cycle of one hour per 24 hours has been found to provide adequate prevention in Sydney.

Special attention should be given to the detailing of ducts in any uninsulated ceiling space to prevent external noise penetrating the occupied spaces by way of the air ducts.

The acoustic design should take account of any additional noise from the ventilation system in the treated space. Because an insulated house has an unnaturally low ambient internal noise level during quiet periods, some occupants can be unusually sensitive to mechanical plant or diffuser noise.

F3.4 Construction

The roof spaces of existing buildings usually contain dust (sometimes of the order of hundreds of kilograms per house) with a high concentration of lead. This dust should be removed and handled in accordance with legislative provisions (e.g. WHS and environmental legislation) before insulation work commences.

Installation and modification of electrical wiring should be performed in accordance with AS/NZS 3000. If wiring has to be covered by insulation, the circuits should be rated and protected as required by AS/NZS 3000. Down-lights in contact with insulation have been the source of ignition. The minimum requirements to be followed where down-lights are pre-existing or have been installed after provision of acoustic insulation are set out in AS/NZS 3000. Failure to address these issues satisfactorily can result in life-threatening situations. In addition, the impact of existing noise insulation components needs to be considered carefully when electrical retrofits are undertaken. Adequate physical separation of heat generating appliances and insulating materials needs to be provided, together with provision for adequate heat dissipation. Excessive heat build-up can initiate fires in the surrounding insulation, in the building structure, or in the appliance itself. Details to prevent these problems might breach the designed acoustic barrier, reducing its effectiveness. Such practical considerations dictate against the use of recessed down-lights where ceilings are close to the profile of the roof.

Where foil-faced acoustic membranes are used, the installation of residual current or earth leakage circuit breakers to all circuits should be considered to protect installers and maintenance workers from inadvertent short circuits to the foil.

Roof structures should be designed or strengthened for the additional insulation and plant loads. For all buildings other than residences of straightforward configuration, the effect of the additional insulation mass upon the stability of the building under earthquake loads should be considered in accordance with AS 1170.4 and AS 3826.

The weight of acoustic windows is much greater than that of other windows. Window fixings should be designed to resist wind and self-weight loads. As a collapsing window is potentially life threatening, positive mechanical fixings should be used and reliance should not be placed on glues. In retrofit situations, strengthening of existing wall frames and window sub-frames is sometimes necessary.

Care should be taken that insulation loads are not transferred to ceiling linings with inadequate load-carrying capacity. Steel straps, mesh, or slats can be installed to support flexible acoustic membranes; in cases of light ceiling construction, fibrous insulation can also require independent support. When installing fibrous insulation to external walls, care should be taken to avoid creating bridges that allow the transfer of water from the outer cladding to the insulation and inner lining.

APPENDIX G

SELECTION OF BUILDING COMPONENTS FOR REDUCTION OF AIRCRAFT NOISE

(Informative)

G1 GENERAL

G1.1 Selection of components

This Appendix presents a method for selecting building components, based on their sound reduction index (R) or weighted sound reduction index (R_w) values, in order to achieve a specified aircraft noise reduction (ANR) value.

NOTE: An explanation of the relationship between weighted sound reduction index, R_w, and sound transmission class, STC, is provided in AS/NZS ISO 717.1.

This Appendix describes a method for the selection of building components and the types of construction which may be necessary to achieve particular ANR values. However, for the detailed design of buildings to meet ANR requirements as specified in this Standard, specialist acoustic advice should generally be sought.

NOTE: As high levels of aircraft noise tend to be dominated by low frequency components, R_w ratings alone are not a reliable guide as to the attenuation properties of building components. The full spectrum information of the building component should be used where an ANR in excess of 30 is required.

G1.2 Number of components

It is assumed that noise from aircraft will, usually, enter a room through only the following components:

(a) Ceiling, if no other rooms are between a ceiling and the building roof.

(b) External wall.

(c) Window.

(d) External door.

To achieve the desired noise reduction for a room, it is necessary to select an adequate construction for each of the components present.

NOTES:

1 The procedure outlined in Paragraph G2 results in equal quantities of noise energy entering through each component present.

2 If more than one type of construction is used for any of the components in Items (a) to (d) above, each type should be treated as an individual component.

3 If floors are elevated so that they are exposed in a way similar to the other components, they should be included and their construction selected in accordance with Paragraph G2 [see Note to Paragraph G2.6.2(c)(iii)].

G1.3 Aircraft noise attenuation by building components

For the purpose of this Appendix, a characteristic of a building component called the aircraft noise attenuation (ANA_c) is defined as the reduction in aircraft noise level, in dB(A), between the level outside and the level inside a room that—

(a) contains an equivalent absorption area numerically the same as the area of that component in the envelope of the room; and

(b) is elsewhere bounded by components assumed to transmit zero aircraft noise.

NOTE: The numerical value of the aircraft noise attenuation of a component depends on both the spectral composition of the aircraft noise and the sound transmission loss of the component. If both these factors are known, the value of ANA_c can be calculated in accordance with Appendix H.

G2 DETERMINE ANA_c REQUIRED OF EACH COMPONENT

G2.1 General

This Paragraph enables the determination of ANA_c required for each component of the room's envelope subject to the conditions that—

(a) the desired aircraft noise reduction, in dB(A), for the room will be achieved; and

(b) there will be an equal quantity of noise energy transmitted through each component (see Note 1 to Paragraph G1.2).

G2.2 Determine number of components (*N*)

By reference to Paragraph G1.2, determine the number of components (N) present in the external envelope of the room or the space. N will usually equal 1, 2, 3, or 4; it will equal more if Note 2 or Note 3 to Paragraph G1.2 applies.

G2.3 Determine the ceiling height (*h*)

Determine the ceiling height (h) of the room in metres.

NOTE: In many instances h will be between 2.6 m and 3.3 m, for which 3 m is a sufficiently accurate approximation.

G2.4 Determine the area ratio (S_c/S_f) for each component

For each component present and for the floor of the room, estimate the surface area to within an accuracy of ±10%. Then determine the ratio of each component's surface area (S_c) to that of the floor of the room (S_f), i.e. the area ratio will be S_c/S_f.

NOTE: The ceiling, if a component, will frequently have an area ratio of 1.

G2.5 Estimate the reverberation time (*T*) of the room, in seconds

For normally furnished and occupied living rooms and bedrooms, T will be approximately 0.5 s. Sparsely furnished and occupied rooms such as bathrooms, kitchens and corridors, may have a T as long as 1 s.

NOTE: If a room is to be protected against intruding noise such as that from aircraft, it is usually not desirable for it to have a reverberation time as long as 1 s. Sound-absorbent materials, such as carpets, drapes, soft furnishings or ceiling tiles, should be introduced to make the environment, when normally occupied, more like that of a typical living room. Exceptions to this may be buildings such as large auditoria and churches, in which longer reverberation times, e.g. 2 s, may be required. In these cases, the value of T is usually known accurately or is predictable as a function of frequency, e.g. the value of T may be taken at 500 Hz or as the average from 100 Hz to 5000 Hz and this value should be used in the application of Paragraph F2.5.

G2.6 Determine the orientation effect (K_c) for each component

G2.6.1 *General*

The orientation effect, K_c, of a building component represents the attenuation of aircraft noise reaching the component due to its orientation with respect to the aircraft. In general, this parameter varies from 0 dB for components directly facing the aircraft to approximately 8 dB for components which are well shielded.

As a first approximation, it may be acceptable to set this parameter to 6 dB for all components. Alternatively, the guidelines below may be used.

G2.6.2 *More accurate determination of K_c*

Approximate allowances for K_c, in decibels, for the level of exposure of building components by sound waves from an aircraft at point of closest passing, may be made by the following procedure:

(a) Estimate the height H of the aircraft above the building in metres, at the point of closest passing, using the appropriate equation as follows:

$$H_L = 0.052DL + 16 - E \text{ (if landing is involved)} \quad \ldots \text{G1}$$

or

$$H_T = 0.11DT - 160 - E \text{ (if taking off is involved)} \quad \ldots \text{G2}$$

where

H_L = height of aircraft landing, in metres

H_T = height of aircraft taking off, in metres

DL = Distance coordinate for building site relative to runway (as specified in Clause 3.1.3) uncorrected for site elevation, in metres

DT = distance coordinate for building site relative to runway (as specified in Clause 3.1.3) uncorrected for site elevation, in metres

E = excess height by which the elevation of the building site exceeds that of the airport, in metres

(b) For each wall of the building, determine on the ground plane the orientation angle θ between the normal (perpendicular) to the wall, and the line to the building from the point beneath that of the closest aircraft passing. Values of θ between ±90°, i.e. corresponding to walls whose outside surface would be directly irradiated by the aircraft at that point, should be estimated to within ±5°. If θ is between 90° and 175° in magnitude, merely note the fact; if θ is between 175° and 180° in magnitude, note whether the wall is facing a parallel one on a nearby building.

(c) The following approximate procedures for estimating orientation effects, K_c, in decibels take into account the angle of sound incidence on directly irradiated surfaces (at closest passing), diffraction around building edges onto surface not directly irradiated, and reflections off the ground and nearby buildings.

In the following equations for K, for aircraft landings let H be H_L; while for aircraft take offs, let H be H_T:

(i) *Roofs*

In the case where a single (skillion) roof plane has been arranged to slope down directly away from the closest passing point with a slope, in degrees, exceeding (arctan (H/DS) − 10), the following value of K may be adopted: K_{RS} = 8 dB.

For all other roof configurations (flat, hip, gable butterfly, sawtooth, and so on), it is recommended that they be treated as simple horizontal planes, for which the orientation effect can be calculated as—

$$K_{RH} = 10 \log_{10} [1 + (DS/H)^2]^{½} \quad \ldots \text{G3}$$

up to a maximum value K_{RH} = 8 dB

(ii) *Walls, windows, doors*

Where the value of θ is between ±90°, let

$$K_w = 10 \log_{10} \left(\frac{\left[1 + (DS/H)^2\right]^{½}}{(DS/H)\cos\theta} \right) \quad \ldots \text{G4}$$

up to a maximum value K_w = 8 dB.

Where θ is outside the range ±90°, let K_w = 8 dB, except where θ is within 5° of ±180° and a parallel wall of a similar or larger building is 6 to 12 m away, in which case let K_w = 3 dB.

(iii) *Floors, elevated or suspended*

The following two well-defined examples represent two rather extreme cases. In both equations, the value of K_w pertaining to the wall of the building having the least magnitude of angle θ is recommended.

(A) *Very exposed floor*—elevation above ground of 2 m or more; site level; subfloor space completely open all around. In this case use the following equation:

$$K_{FE} = K_{RH} + K_w \quad \ldots \text{G5}$$

up to a maximum value K_{FE} = 8 dB.

(B) *Well-shielded floor*—elevation above ground 1 m or less; site level; subfloor space walled in completely except for the minimum open venting required by regulations. In this case use the following equation:

$$K_{FS} = (K_w + 5) \quad \ldots \text{G6}$$

NOTE: Other practical suspended floor designs will tend to result in orientation effects intermediate between those shown in Items (A) and (B). Since the two estimates K_{FE} and K_{FS} do not differ by more than 5 dB, a subjective interpolation between these two values would be appropriate for a construction which appears to offer an intermediate degree of shielding.

G2.7 Determine the aircraft noise attenuation required of each component

Determine the aircraft noise attenuation required of each component to achieve the specified aircraft noise reduction, using the following equation:

$$ANA_c = ANR + 10 \log_{10} [(S_c/S_f) \times (3/h) \times 8TN] - K_c \quad \ldots \text{G7}$$

where

ANA_c = the aircraft noise attenuation required of the component, in dB(A)

ANR = required aircraft noise reduction, in dB(A)

S_c/S_f = area ratio of the component

h = ceiling height of room, in metres

T = reverberation time of room, in seconds

N = number of components

K_c = orientation effect for the component, in decibels

G3 SELECT MATERIALS AND CONSTRUCTIONS HAVING THE ANA_c REQUIRED

G3.1 Determination of ANA_c

The ANA_c value of a particular building material or construction may be determined from the sound reduction index (R) values of that material or construction over a range of frequencies, together with spectral data for the aircraft noise event under consideration. A method for performing this calculation is set out in Appendix H.

NOTES:

1 If either the relevant sound reduction index data or aircraft noise spectral data are unavailable, an approximation to the ANA_c value for the building component may be derived from the weighted sound reduction index (R_w) or weighted apparent sound reduction index (R'_w) of the material or construction (see AS/NZS ISO 717.1). These values are generally quoted in reports of sound reduction index tests, and in information supplied by manufacturers. If these data are used, the ANA_c value for the component may be approximated as—

$$ANA_c = R_w - 5 \text{ or } R'_w - 5 \quad \ldots \text{G8}$$

2 The average spectral allowance of 5 dB adopted here applies to many aircraft types and movements and is based on—

(a) measurements of their respective maximum noise spectra at points near major airports; and

(b) computations of how these spectra would interact with the sound reduction index versus frequency characteristics of a large number of building components (see Appendix H).

3 Design procedures involving the optimization of costs and building performance, for which aircraft noise reduction may be one factor, are beyond the scope of this Standard. For example, the final selection of components may be made after consideration of the relative merits of various area ratios for the components, or departures from the principle of equal acoustic energy transmission per component.

G3.2 Limitations of procedure

Most components identified as probably suitable by the procedure given in Paragraph G3.1 will actually provide ANA_c values within ±3 dB(A) of the value desired, provided builders' or sub-contractors' methods and procedures are appropriately specified and supervised; errors of 5 dB(A) may be expected if these precautions are not taken into account. For buildings where errors of this magnitude can be tolerated, the selection of components may be made from those identified as providing ANA_c values equal to or greater than the values determined in Paragraph G2.

More accurate ANA_c values than those derived from R_w or R'_w values may be computed directly from sound transmission losses by the method given in Appendix H. This procedure should be adopted when greater confidence in the ANA_c values is required.

APPENDIX H

DIRECT COMPUTATION OF ANA_c

(Informative)

Where spectral data for the relevant aircraft noise and for the sound reduction index value for the component under consideration are both available, ANA_c may be predicted from the following equation:

$$ANA_c = 10\log_{10}\sum_{f_{min.}}^{f_{max.}}\text{antilog}_{10}\frac{L_f + C_f}{10} - 10\log_{10}\sum_{f_{min.}}^{f_{max.}}\text{antilog}_{10}\frac{L_f + C_f - R_f}{10} \quad \ldots \text{H1}$$

where

ANA_c = aircraft noise attenuation that the component of the particular form of construction under consideration will provide against noise having that spectrum, in dB(A)

L_f = relative spectral level for the noise concerned, in the one-third octave band centred on frequency f

C_f = value of the A-weighting function at the frequency f, as given in AS IEC 61672.1, in decibels

R_f = value of the sound reduction index in the one-third octave band centred on frequency f, in decibels

f = the set of standard one-third octave band centre frequencies ranging from $f_{min.}$ to $f_{max.}$ corresponding to the range available in the published weighted sound reduction index data for the component

NOTE: It is desirable to use the range 100 Hz to 5000 Hz inclusive, but overseas data often limit the range to either 100 Hz to 3150 Hz or 125 Hz to 4000 Hz. Analogous computation in 1/1 octave bands would be adequate, but the sound reduction index data would be required in that form.

NOTES

Standards Australia

Standards Australia develops Australian Standards® and other documents of public benefit and national interest. These Standards are developed through an open process of consultation and consensus, in which all interested parties are invited to participate. Through a Memorandum of Understanding with the Commonwealth Government, Standards Australia is recognized as Australia's peak non-government national standards body. Standards Australia also supports excellence in design and innovation through the Australian Design Awards.

For further information visit www.standards.org.au

Australian Standards®

Committees of experts from industry, governments, consumers and other relevant sectors prepare Australian Standards. The requirements or recommendations contained in published Standards are a consensus of the views of representative interests and also take account of comments received from other sources. They reflect the latest scientific and industry experience. Australian Standards are kept under continuous review after publication and are updated regularly to take account of changing technology.

International Involvement

Standards Australia is responsible for ensuring the Australian viewpoint is considered in the formulation of International Standards and that the latest international experience is incorporated in national Standards. This role is vital in assisting local industry to compete in international markets. Standards Australia represents Australia at both the International Organization for Standardization (ISO) and the International Electrotechnical Commission (IEC).

Sales and Distribution

Australian Standards®, Handbooks and other documents developed by Standards Australia are printed and distributed under licence by SAI Global Limited.
